

# i.MX51 VPU Application Programming Interface Windows Embedded CE 6.0 Reference Manual

## 1 Introduction

This section presents general information about the i.MX51 Video Processing Unit (VPU).

### 1.1 Overview

The i.MX51 Video Processing Unit (VPU) is a high performance multi-standard video decoder and encoder engine that performs multiple standard decoding and encoding operations. The VPU codec is fully compliant with H.264 BP/MP/HP, VC-1 SP/MP/AP, MPEG-4 SP/ASP except GMC, Divx(Xvid), MPEG-1/2 and MJPEG decoding and encoding. The VPU supports up to HD (1920×1088) decoding and SD (720×576) encoding. It can encode or decode multiple video clips with multiple standards simultaneously. A block diagram of the i.MX51 VPU is shown in [Figure 1](#).

The VPU connects with the system through the 32-bit AMBA3 APB bus for system control and the 64-bit AMBA3 AXI for data throughput. The VPU also takes advantage of on-chip memories to achieve high performance.

Most video hardware blocks in the VPU are optimally designed for shared usage between different video standards,

which provides ultra low power and low gate count with powerful performance. As shown in Figure 1, the VPU has a 16-bit DSP core, the BIT processor, which controls the internal video codec operations.

For simple and efficient control of the VPU by the host processor, the VPU provides a set of registers called the host interface registers. Most commands and responses between the host processor and the VPU are transmitted through the host interface registers. Stream data and some output picture data are directly accessed by the host processor and the VPU. For a more comprehensive way of controlling the VPU, a set of API functions are provided that includes all of the required operations from the host processor side.

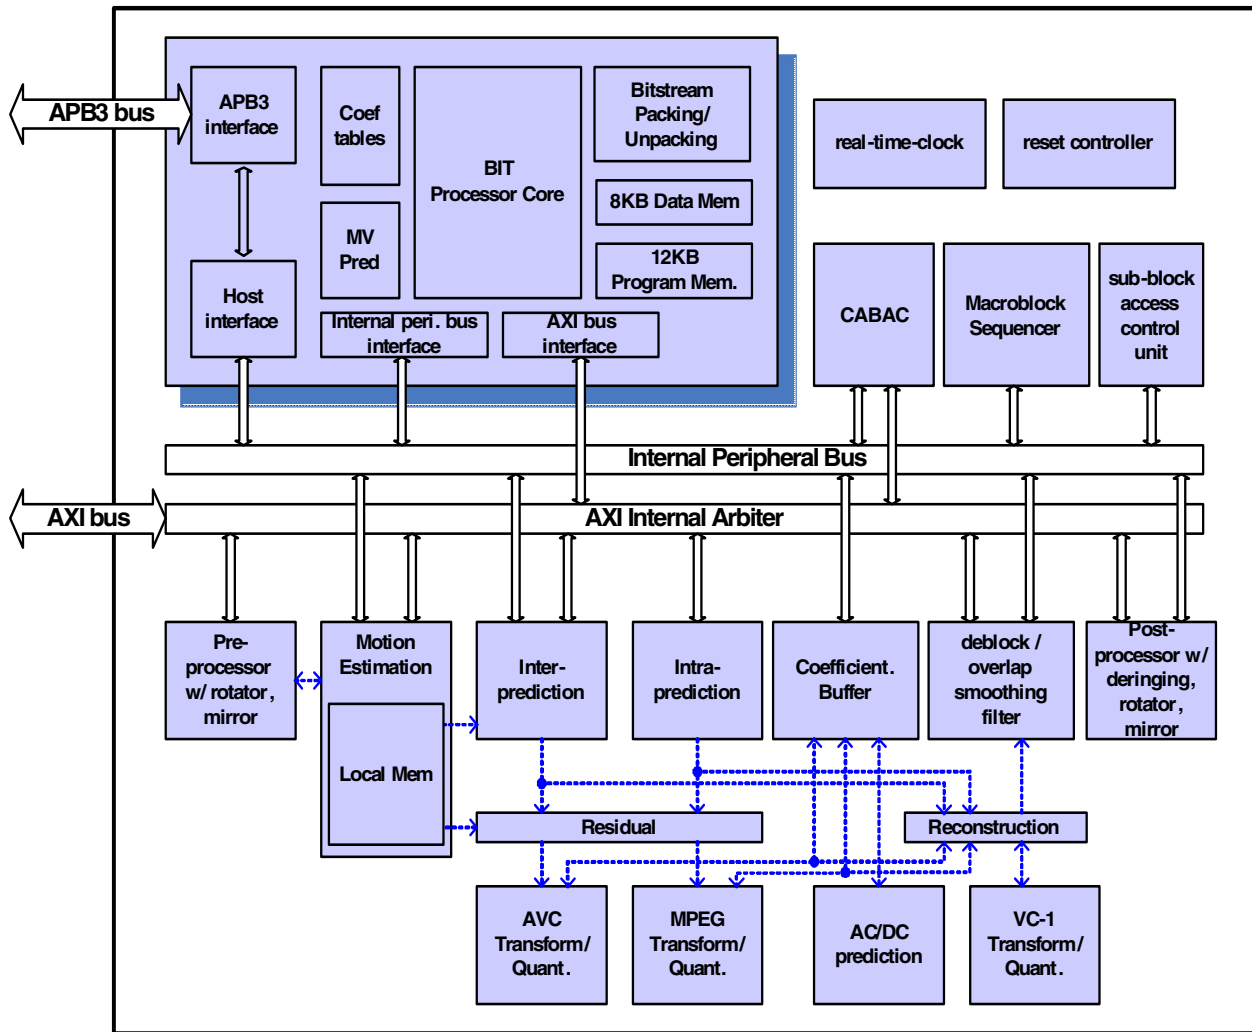

Figure 1. i.MX51 VPU Block Diagram

## 1.2 Main Features

The VPU is fully compliant with H.264 BP/MP/HP, VC-1 SP/MP/AP, MPEG-4 SP/ASP except GMC, Divx (Xvid) and MPEG-1/2 and MJPEG. Image sizes up to HD (1920×1088 or 2048×1024) are supported for decoding and up to SD (720×576) are supported for encoding. The VPU supports various error resilience tools and also supports multiple decoding and full duplex multi-party-call simultaneously. The

VPU provides programmability, flexibility and ease of upgrade in decoding and encoding or host interface because all of the controls in the decoding and encoding process and host interface are implemented as firmware in the programmable BIT processor.

The detailed features of the VPU are as follows:

- Encoding
  - $[\pm 32, \pm 16]$  1/2 and 1/4-pel accuracy motion estimation
  - 16×16, 16×8, 8×16 and 8×8 block sizes
  - Configurable block sizes
  - Only one reference frame for motion estimation
  - Unrestricted motion vector
  - Prediction
    - MPEG-4 AC/DC prediction
    - H.264/AVC intra-prediction
  - H.263 Annex J, K (RS=0 and ASO=0), and T
  - Error resilience tools
    - MPEG-4 resync marker and data-partitioning with RVLC (fixed number of bits/macroblocks between macroblocks)
    - CIR (Cyclic Intra Refresh)
    - Bit-rate control (CBR and VBR)
  - Up to 4:2:2 format for MJPEG encoder
  - 48×32 pixel minimum encoding image size (48 pixels horizontal and 32 pixels vertical)
- Decoding
  - H.264
    - Fully compatible with the ITU-T Recommendation H.264 specification in BP/MP and HP
    - CABAC/CAVLC
    - Variable block size—16×16, 16×8, 8×16, 8×8, 8×4, 4×8 and 4×4
    - Error detection, concealment and error resilience tools
  - VC1
    - All VC-1 profile features—SMPTE Proposed SMPTE Standard for Television: VC-1 Compressed Video Bitstream format and Decoding Process
    - Simple/Main/Advanced Profile
    - Multi-resolution (dynamic resolution) is not processed inside the video decoder
  - MPEG-4
    - Simple/Advanced Simple profile except GMC
    - H.263 Baseline Profile
    - Divx version 3.x to 6.x
    - Xvid
  - MPEG-2

- Fully compatible with ISO/IEC 13182-2 MPEG2 specification in main profile
  - I,P and B frame
  - Field coded picture (interlaced) and frame coded picture
- RV-8/9/10
  - Fully compatible with RV-8/9/10 except re-sampling feature
- MJPEG
  - Baseline ISO/IEC 10918-1 JPEG compliance
  - JFIF 1.02 input format with up to 3 components
  - 8-bit samples for each component
  - Support up to 4:4:4
- 64×64 pixel minimum decoding size; 16×16 pixels is supported for MJPG decode
- Value added features
  - MPEG-2 partial acceleration
  - De-ringing
  - Pre/Post rotator/mirror
  - Built-in de-blocking filter for MPEG-2/MPEG-4 and Divx
- Programmability
  - 16-bit DSP processor dedicated to processing bitstream and controlling the codec hardware
  - General purpose registers and interrupt for communication to and from a host processor
- Performance
  - All video decoder standards up to 1920×1088 @ 30 fps at 133 MHz
  - All video encoder standards up to 720×480 @ 30 fps (720×576 @ 25 fps) at 66 MHz
  - MJPEG decoder (4:4:4) supports 32 M pixel per second and the image size is up to 8196×8196 @ 133 MHz
  - MJPEG encoder (4:2:2) supports 64 M pixel per second and the image size is up to 8196×8196 @ 133 MHz
  - MJPG decoder on 4:2:0 supports 64 M pixel per second @ 133MHz
  - MJPG encoder on 4:2:0 supports 85.3 M pixel per second @ 133MHz
- Interrupt
  - Interrupt from and to external host processor or interrupt controller

## 1.3 Programmability

The VPU has an internal DSP called the BIT processor which controls the internal hardware blocks for video decoder operations. The operation of the BIT processor is determined by the dedicated microcode called the BIT firmware. The VPU has a complete set of BIT firmware codes as well as a complete set of VPU control functions, called the VPU API. Therefore, application developers do not need to manage codec-specific issues on host processor.

### 1.3.1 Frame-Based Processing

The BIT processor completes decoding operations on a frame-by-frame basis, which allows low level independency of VPU operations to the host processor. While frame operations are running, there is no need for communication between the host processor and the VPU. Therefore, the VPU does not burden the host processor during decoder operations.

After issuing a picture processing command, the host application performs its own operations until it is ready for the next picture processing operation or until it receives an interrupt from VPU informing the host processor of completion of the picture processing.

### 1.3.2 Program Memory Management

The VPU has its own program memory to load BIT firmware for supporting application-specific operations. In order to use this internal memory efficiently, the BIT firmware has a dynamic re-loading scheme, which enables the VPU to have a small amount of program memory.

For example, if a MPEG-2 decoder operation is running on the VPU, then the VPU program memory is filled by the MPEG-2 decoder firmware in the VPU. If a H.264 decoder operation is newly issued, then the BIT processor automatically loads the H.264 decoder firmware from the SDRAM to program memory.

Because of the frame-based operation of VPU, the maximum rate of this dynamic reloading operation is approximately 30 times per second in a single instance decoder case. Since the amount of BIT firmware for one decoder standard is smaller than 16 Kbytes, this is not a large burden for the VPU operations in performance and memory bandwidth.

### 1.3.3 Multi-Instances

The VPU supports multiple instances which can be helpful for multi-channel decoder applications. In order to support this multi-instance operation, the BIT processor uses an internal context parameter set for each decoder instance. When creating a new instance and starting a picture processing operation, a set of context parameters is created and updated automatically within the VPU. This internal context management scheme allows different decoder tasks running on the host processor to control VPU operations independently with their own instance numbers.

When creating a new instance, an application task receives a new handle specifying an instance if a new handle is available on the VPU. All the subsequent operations for the given application task are handled separately by the VPU using this task-specific handle. When writing a VPU driver, this handle can be regard as a device-ID or a port-ID of the VPU for each task. Since the VPU can only perform one picture processing task at a time, the application task should check if the VPU is ready before starting a new picture operation. An application can easily terminate a single task on the VPU by calling a function for closing a certain instance.

## 2 Host Interface

This section presents a general description of the host interfaces provided for a host processor to control the i.MX51 VPU.

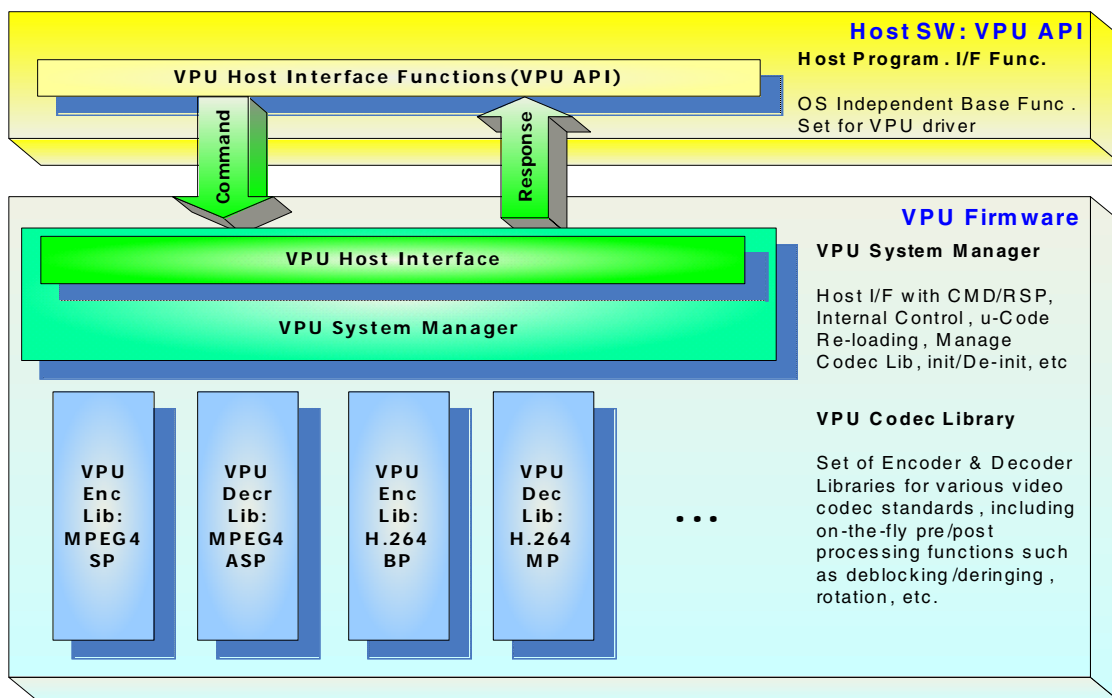

### 2.1 Host Interface Overview

This section presents an overview of the host interfaces.

#### 2.1.1 Communication Models

The VPU requires a dedicated path for exchanging data and/or messages between the host processor and the VPU. The VPU uses shared memory for exchanging data between the host processor and the VPU. This shared memory is accessible through the ABMA host bus. Bitstream data and frame data are exchanged using this shared memory space.

Independent of data exchange path, a dedicated path for messages between the host processor and the VPU is provided using a set of VPU registers called the host interface registers. All commands and responses between the host processor and the VPU are exchanged through these registers as shown in Figure 2.

**Figure 2. Data and Message Exchange Between Host and VPU**

All of the bitstream and picture data is accessed directly by the host processor and the VPU. The related information about the data transfer as well as command and responses is exchanged through the host interface. The host interface of the VPU uses a set of registers accessible from the host processor. Some of these host registers are used for exchanging actual command and responses and other registers are used to give information about the internal status of VPU to host processor. Firmware running on the BIT processor is well-optimized for a given set of commands and responses.

## 2.1.2 Data Handling

All of the pixel data or stream data transactions are performed by the host processor or the VPU through the shared memory space in the SDRAM. In order to assure safe transactions between the host processor and the VPU, all the required information is stored in the host interface registers. Generally, these transactions are one-directional transactions—the host or VPU writes the data and the other reads the data on a single data buffer. Therefore, transactions are easily and safely controlled using a pair of read and write pointers.

As well as the common data buffers in shared memory, the BIT processor requires a certain amount of memory for processing, called the working buffer. The working buffer can only be accessed by the VPU. In addition, the frame buffers used in picture decoding are managed by the VPU exclusively, which ensures safe decoding in the VPU.

For proper streaming, the available free space in the decoder stream buffer can be accessed using the buffer read pointer, write pointer and buffer size. A set of APIs is provided for this purpose that can be called by the application at anytime.

## 2.1.3 Host Interface Registers

A set of commands is provided for controlling codec operations on a frame-by-frame basis as well as the corresponding responses. The host interface registers can be partitioned into three categories as follows:

- BIT processor control registers—Update or show BIT processor status to the host processors. Most of these registers are used for initializing the BIT processor during boot-up.
- BIT processor global registers—Store all the global variables which are reserved even while an active instance is changed. All the buffer addresses and some global options are safely stored in these registers.
- BIT processor command I/O registers—Overwritten or updated whenever a new command is transmitted from the host processor. All the commands with input arguments and all the corresponding responses with return values are handled using these registers.

In addition, command I/O registers are used in a pre-defined way for each command to control the VPU.

## 2.2 API-Based VPU Control

Host applications generally control the VPU through a set of pre-defined APIs by sending a command and corresponding arguments to the VPU. After receiving an interrupt from the VPU, signalling the completion of the requested operation, the host application acquires the results as shown in [Figure 3](#).

Each API definition includes the requested command as well as the input and output data structure. The given command from the API function is always written on a dedicated I/O register, but the input and output data structure is transmitted through a set of command I/O registers that contain the input arguments

and output results. Therefore, application developers do not need know the details of the host register definitions and usage.

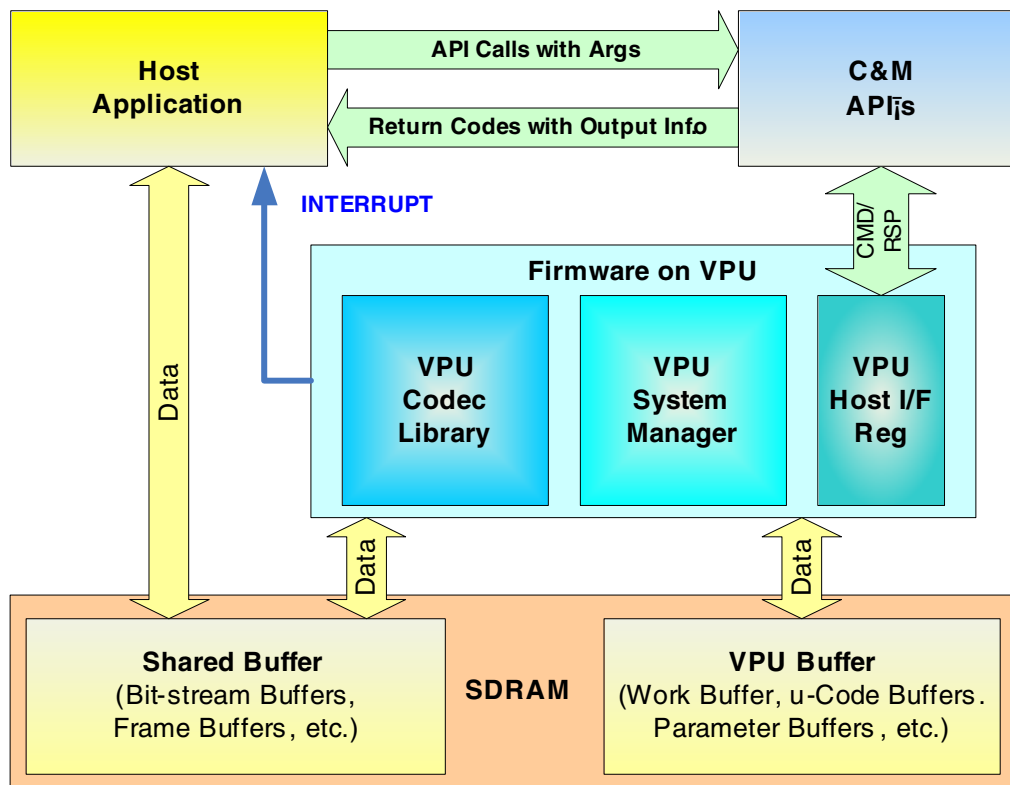

Figure 3. Software Control Model of VPU from Host Application

## 3 i.MX51 VPU Driver API Reference

### 3.1 API Features

A set of API functions is provided to efficiently control the VPU. The VPU API covers all functions of the i.MX51 VPU. This API-based approach speeds up the development process of application software. Important features of the API for the i.MX51 VPU are summarized in the following sections.

#### 3.1.1 Simple Software Control

The i.MX51 VPU API provides a simple way to control the i.MX51 VPU and avoid errors in application software. The host application does not need to know the details of the i.MX51 VPU internal operations. For example, in order to initialize the VPU, an application simply calls an API for initialization, **vpui\_Init()**, and no additional information is required for calling this API. The **vpui\_Init()** API performs all the required steps for initializing the i.MX51 VPU. When issuing a picture decoder operation, the application simply changes some variables included in the well-defined input data structure.

### 3.1.2 Handling Multi-Instances

The i.MX51 VPU supports multiple instances for decoding and encoding at the same time, which can be used in multiple decoding and encoding and multi-party call applications. To support multi-instance operations, the i.MX51 VPU API provides a full set of functions for handling the instances with ease. When opening a new instance, an application receives a handle specifying the new instance, if a new handle is available at that time. The operations for a given instance are separately controlled using the corresponding handle. An application can easily terminate a single task on the VPU by calling a function for closing a certain instance.

### 3.1.3 Frame-Based Codec Processing

The i.MX51 VPU completes decoding and encoding operation on a frame-by-frame basis, which enables low level independency of VPU operations on the host processor. While frame processing operation are running, there is no need for communication between the host processor and the VPU. Therefore, the VPU does not burden the host processor during decoding and encoding operations.

## 3.2 Type Definitions

This section describes the types and structures used in the VPU API.

### 3.2.1 Type Definitions

This section describes the common data types used in the VPU API functions.

#### 3.2.1.1 Uint8

```
typedef unsigned char Uint8;
```

##### Description

8-bit unsigned integer type used for declaring pixel data

#### 3.2.1.2 Uint16

```
typedef unsigned short Uint16;
```

##### Description

16-bit unsigned integer type

#### 3.2.1.3 Uint32

```
typedef unsigned int Uint32;
```

##### Description

32-bit unsigned integer type used for declaring unsigned variables with wide ranges such as the size of a buffer

### 3.2.1.4 PhysicalAddress

```
typedef Uint32 PhysicalAddress;
```

#### Description

Represents physical addresses that are recognizable by the VPU. In general, the VPU hardware does not know about the virtual address space that is set and handled by the host processor. The virtual addresses are translated into physical addresses by the Memory Management Unit (MMU). Data buffer addresses, such as input bitstream buffer or frame buffer, are given to VPU as an address in the physical address space.

### 3.2.1.5 CodStd

```
typedef enum {
    STD_AVC,
    STD_VC1,
    STD_MPEG2,
    STD_MPEG4,
    STD_H263,
    STD_DIV3,
    STD_MJPG,
    STD_RV
} CodStd;
```

#### Description

Enumeration for declaring code standard type variables. The following video standards are supported by the VPU:

- AVC (H.264) BP/MP/HP
- VC-1 SP/MP/AP
- MPEG-2, MPEG-1
- MPEG4 SP/ASP
- H.263 Profile 3
- Divx3
- RealVideo 8/9/10

#### NOTE

The MPEG-1 decoder operation is handled as a special case of the MPEG-2 decoder. The RealVideo 8/9/10 decoder is only available for licensed customers.

### 3.2.1.6 RetCode

```
typedef enum {
    RETCODE_SUCCESS,
    RETCODE_FAILURE,
    RETCODE_INVALID_HANDLE,
    RETCODE_INVALID_PARAM,
    RETCODE_INVALID_COMMAND,
    RETCODE_ROTATOR_OUTPUT_NOT_SET,
}
```

```

    RETCODE_ROTATOR_STRIDE_NOT_SET,
    RETCODE_INVALID_FRAME_BUFFER,
    RETCODE_INSUFFICIENT_FRAME_BUFFERS,
    RETCODE_INVALID_STRIDE,
    RETCODE_WRONG_CALL_SEQUENCE,
    RETCODE_CALLED_BEFORE,
    RETCODE_NOT_INITIALIZED,
    RETCODE_FAILURE_TIMEOUT,
    RETCODE_BUSY,
    RETCODE_IDLE,
    RETCODE_REPORT_BUF_NOT_SET
} RetCode;

```

## Description

Enumeration for declaring the return codes from API function calls. The meaning of each return code is the same for all API functions, but the reason of non-successful return might be different. Details of the reasons for the return code are described in [Section 3.3, “API Definitions.”](#) Table 1 shows the basic meaning of each return code.

**Table 1. Return Codes**

Code	Description
RETCODE_SUCCESS	Operation successful
RETCODE_FAILURE	Operation not successfully; this value is returned when an un-recoverable decoder error occurs such as a header parsing error
RETCODE_INVALID_HANDLE	Given handle for current API function call is invalid, for example, not initialized yet or improper function call for the given handle
RETCODE_INVALID_PARAM	Given argument parameters (for example, input data structure) is invalid (not initialized yet or not valid anymore)
RETCODE_INVALID_COMMAND	Given command is invalid, for example, undefined or not allowed in the given instance
RETCODE_ROTATOR_OUTPUT_NOT_SET	Rotator output buffer is not allocated even though rotation is enabled
RETCODE_ROTATOR_STRIDE_NOT_SET	Rotator stride is not provided even though rotation is enabled
RETCODE_INVALID_FRAME_BUFFER	Certain frame buffer pointers are invalid (not initialized yet or not valid)
RETCODE_INSUFFICIENT_FRAME_BUFFERS	Given numbers of frame buffers are not enough for the operations of the given handle. This return code is only received when calling the <b>DecRegisterFrameBuffer()</b> function
RETCODE_INVALID_STRIDE	Given stride is invalid (for example, 0, not a multiple of 8 or smaller than the picture size). This return code is only allowed in API functions which set stride
RETCODE_WRONG_CALL_SEQUENCE	Current API function call is invalid considering the allowed sequences between API functions (for example, missing one crucial function call before this function call)
RETCODE_CALLED_BEFORE	Multiple calls of current API function for a given instance are invalid
RETCODE_NOT_INITIALIZED	VPU is not initialized yet. Before calling any API functions, the initialization API function, <b>vpu_Init()</b> , should be called

Table 1. Return Codes (continued)

Code	Description
RETCODE_FAILURE_TIMEOUT	Hardware is already busy with another operation and unavailable for current API calling or something is wrong with the VPU
RETCODE_BUSY	VPU is busy with some operation
RETCODE_IDLE	VPU is idle
RETCODE_REPORT_BUF_NOT_SET	The VPU supports information reporting for MV/MB/SLICE/frame buffer status/user data. In this case, the host application must allocate buffers to save this information. These buffers can be in the virtual memory in the user space. If these buffers are not allocated, but the corresponding report is enabled, this error is returned. If the host application does not use these reports, not to enable the report feature.

### 3.2.1.7 CodecCommand

```
typedef enum {
    ENABLE_ROTATION,
    DISABLE_ROTATION,
    ENABLE_MIRRORING,
    DISABLE_MIRRORING,
    SET_MIRROR_DIRECTION,
    SET_ROTATION_ANGLE,
    SET_ROTATOR_OUTPUT,
    SET_ROTATOR_STRIDE,
    DEC_SET_SPS_RBSP,
    DEC_SET_PPS_RBSP,
    ENABLE_DERING,
    DISABLE_DERING,
    DEC_SET_REPORT_BUFSTAT,
    DEC_SET_REPORT_MBINFO,
    DEC_SET_REPORT_MVINFO,
    DEC_SET_REPORT_USERDATA,
    ENC_GET_SPS_RBSP,
    ENC_GET_PPS_RBSP,
    ENC_PUT_MP4_HEADER,
    ENC_PUT_AVC_HEADER,
    ENC_GET_VOS_HEADER,
    ENC_GET_VO_HEADER,
    ENC_GET_VOL_HEADER,
    ENC_SET_INTRA_MB_REFRESH_NUMBER,
    ENC_ENABLE_HEC,
    ENC_DISABLE_HEC,
    ENC_SET_SLICE_INFO,
    ENC_SET_GOP_NUMBER,
    ENC_SET_INTRA_QP,
    ENC_SET_BITRATE,
    ENC_SET_FRAME_RATE,
    ENC_SET_REPORT_MBINFO,
    ENC_SET_REPORT_MVINFO,
    ENC_SET_REPORT_SLICEINFO
} CodecCommand;
```

## Description

Special enumeration type for configuration commands from the host processor to the VPU. Most of these commands are called occasionally (not periodically) for changing the VPU operation configuration. Details of these commands are presented in [Section 3.3.3.9, “vpu\\_EncGiveCommand\(\).”](#)

### 3.2.1.8 MirrorDirection

```
typedef enum {
    MIRROR_NONE,
    MIRROR_VER,
    MIRROR_HOR,
    MIRROR_HOR_VER
} MirrorDirection;
```

## Description

Enumeration type for representing the mirroring direction

### 3.2.1.9 Mp4HeaderType

```
typedef enum {
    VOL_HEADER,
    VOS_HEADER,
    VIS_HEADER
} Mp4HeaderType;
```

## Description

Special enumeration type for MPEG-4 top-level header classes such as visual sequence header, visual object header and video object layer header

### 3.2.1.10 AvcHeaderType

```
typedef enum {
    SPS_RBSP,
    PPS_RBS
} AvcHeaderType;
```

## Description

Special enumeration type for AVC parameter sets such as sequence parameter set and picture parameter set

### 3.2.1.11 EncHandle

```
typedef EncInst * EncHandle;
```

## Description

Dedicated type for encoder handles returned when an encoder instance is opened. An encoder instance can be referred to by the corresponding handle. EncInst is a type managed internally by the API and the application does not need to use it.

### 3.2.1.12 DecHandle

```
typedef DecInst * DecHandle;
```

#### Description

Dedicated type for decoder handles returned when a decoder instance is opened. A decoder instance can be referred to by the corresponding handle. DecInst is a type managed internally by API and the application does not need to use it.

## 3.2.2 Data and Structure Definitions

This section describes the data and structure definitions used in the VPU API functions.

### 3.2.2.1 FrameBuffer

```
typedef struct {
    PhysicalAddress bufY;
    PhysicalAddress bufCb;
    PhysicalAddress bufCr;
    PhysicalAddress bufMvCol;
} FrameBuffer;
```

#### Description

Data structure for representing frame buffer pointers for each color component

bufY	Address for Y component in the physical address space
bufCb	Address for Cb component in the physical address space
bufCr	Address for Cr component in the physical address space
bufMvCol	Address for co-located motion vector buffers in the physical address space

The host application must allocate contiguous physical memory from the SDRAM space for the components using this data structure. All four addresses must be 8-byte aligned. One pixel value of a component occupies one byte and the frame data is in YCbCr 4:2:0 format for H.264, H.264 and MPEG-4 codecs. The sizes of the Cb and Cr buffers are 1/4 the size of the Y buffer size for H.264, H.263 and MPEG-4 codecs. For MJPEG, the frame data format can be YCbCr 4:2:0, 4:2:2 horizontal, 4:2:2 vertical, 4:4:4 and 4:0:0 and the sizes of the Cb and Cr buffers vary. The co-located motion vector is only required for B-frame decoding in MPEG-2, AVC MP/HP, MPEG-4 ASP, VC-1 MP/AP, RealVideo 8/9/10, and so on.

### 3.2.2.2 Rect

```
typedef struct {
    Uint32 left;
    Uint32 top;
    Uint32 right;
    Uint32 bottom;
} Rect;
```

#### Description

Data structure for representing a rectangular window in a frame

left	Horizontal pixel offset of top-left corner of rectangle from top-left corner of a frame
top	Vertical pixel offset of top-left corner of rectangle from top-left corner of a frame
right	Horizontal pixel offset of bottom-right corner of rectangle from top-left corner of a frame
bottom	Vertical pixel offset of bottom-right corner of rectangle from top-left corner of a frame

This structure is provided to the host application to specify a display window for the H.264 cropping option. Each value is offset from the top-left corner of the frame; therefore, all values are positive.

### 3.2.2.3 EncHeaderParam

```
typedef struct {
    PhysicalAddress buf;
    int size;
    int headerType;
} EncHeaderParam;
```

#### Description

Structure used for adding a header syntax layer to the encoded bit stream. The parameter headerType is the input parameter to the VPU and the other two parameters are returned from the VPU after completing the requested operation. If the encoder dynamic buffer allocation option is enabled as well as the stream buffer reset option, the parameters buf and size are also input parameters. In this case, the host application must allocate the contiguous physical buffer to save the encoded header syntax and pass its physical base address and size to the VPU. Otherwise the encoded header syntax is saved in the bit stream buffer passed to the VPU while calling **vpv\_EncOpen()** to open encoder instance.

### 3.2.2.4 EncParamSet

```
typedef struct {
    Uint32 *paraSet;
    int sizeInByte;
} EncParamSet;
```

#### Description

Structure used when the host processor requires SPS or PPS data from an encoder instance. The resulting SPS or PPS data is used in an application as a type of out-of-band information. The size of the buffer pointed to by paraSet should be large enough to save SPS and/or PPS data. The proposed size is not smaller than 100 bytes and is a multiple of 8-byte. The size of returned SPS and/or PPS data is saved in sizeInByte.

### 3.2.2.5 EncMp4Param

```
typedef struct {
    int mp4_dataPartitionEnable;
    int mp4_reversibleVlcEnable;
    int mp4_intraDcVlcThr;
    int mp4_hecEnable;
    int mp4_verid;
} EncMp4Param;
```

## Description

Data structure for configuring MPEG4-specific parameters in encoder applications

mp4_dataPartitionEnable	0 = disable, 1 = enable
mp4_reversibleVlcEnable	0 = disable, 1 = enable
mp4_intraDcVlcThr	Value of intra_dc_vlc_thr in MPEG-4 part 2 standard, valid range is 0–7
mp4_hecEnable	0 = disable, 1 = enable
mp4_verid	Value of MPEG-4 part 2 standard version ID, version 1 and 2 are allowed

### 3.2.2.6 EncH263Param

```
typedef struct {
    int h263_annexJEnable;
    int h263_annexKEnable;
    int h263_annexTEnable;
} EncH263Param;
```

## Description

Data structure for configuring H.263-specific parameters in encoder applications

h263_annexJEnable	0 = disable, 1 = enable
h263_annexKEnable	0 = disable, 1 = enable
h263_annexTEnable	0 = disable, 1 = enable

### 3.2.2.7 EncAvcParam

```
typedef struct {
    int avc_constrainedIntraPredFlag;
    int avc_disableDeblk;
    int avc_deblkFilterOffsetAlpha;
    int avc_deblkFilterOffsetBeta;
    int avc_chromaQpOffset;
    int avc_audEnable;
    int avc_fmoEnable;
    int avc_fmoSliceNum;
    int avc_fmoType;
    int avc_fmoSliceSaveBufSize;
} EncAvcParam;
```

## Description

Data structure for configuring AVC-specific parameters in encoder applications

avc_constrainedIntraPredFlag	Constrained_intra_pred_flag in picture parameter set 0 = disable, 1 = enable
avc_disableDeblk	Disable_deblocking_filter_idc in slice header 0 = enable, 1 = disable, 2 = disable deblocking filter at slice boundaries
avc_deblkFilterOffsetAlpha	slice_alpha_c0_offset_div2 in slice header, range is –6 to 6
avc_deblkFilterOffsetBeta	slice_beta_offset_div2 in slice header, range is –6 to 6

avc_chromaQpOffset	chroma_qp_index_offset in picture parameter set, range is -12 to 12
avc_audEnable	Enable or disable encode H.264 Access Unit Delimiter (AUD) RBSP used to simplify the detection of the picture boundary 0 = disable, 1 = enable and the encoder generates AUD RBSP at the start of every picture
avc_fmoEnable	Not used on the i.MX51 since FMO encoding is not supported
avc_fmoSliceNum	Not used on the i.MX51 since FMO encoding is not supported
avc_fmoType	Not used on the i.MX51 since FMO encoding is not supported
avc_fmoSliceSaveBufSize	Not used on the i.MX51 since FMO encoding is not supported

### 3.2.2.8 EncMjpgParam

```
typedef struct {
    int mjpg_sourceFormat;
    int mjpg_restartInterval;
    int mjpg_thumbNailEnable;
    int mjpg_thumbNailWidth;
    int mjpg_thumbNailHeight;
    Uint8 * mjpg_hufTable;
    Uint8 * mjpg_qMatTable;
} EncMjpgParam;
```

#### Description

Data structure for configuring MJPEG-specific parameters in encoder applications

mjpg_sourceFormat	Chroma format. The format means chrominance size of source image and can be a value between 0 and 4: 0 = 4:2:0, 1 = 4:2:2 horizontal, 2 = 4:2:2 vertical, 3 = 4:4:4, 4 = 4:0:0
mjpg_restartInterval	Value for representing interval of restart marker in Mbytes
mjpg_thumbNailEnable	0 = disable, 1 = enable and the encoder enables thumbnail encoding
mjpg_thumbNailWidth	Variable representing the width of the thumbnail to be encoded in pixels. This variable can be between 0 and source image width, must be over a specific value and must be a multiple of the value shown in <a href="#">Table 2</a> .

**Table 2. mjpg\_thumbNailWidth and mjpg\_thumbNailHeight Values**

Format	Value
4:2:0	16
4:2:2	16
2:2:4	8
4:4:4	8
4:0:0	8

**mjpg\_thumbNailHeight** Variable representing the height of the thumbnail to be encoded in pixels. This variable can be between 0 and source image height, must be over a specific value and be a multiple of the value shown in [Table 2](#).

**mjpg\_hufTable** Variable representing a pointer to an address in the Huffman table. The Huffman table coefficients are saved in pre-defined format as shown in [Table 3](#).

**Table 3. Huffman Table Format**

Offset Address	0	1	2	3	Description
0x000	Y_DCBits[3]	Y_DCBits[2]	Y_DCBits[1]	Y_DCBits[0]	Luminance DC BitLength
...	...	...	...	...	
0x00C	Y_DCBits[15]	Y_DCBits[14]	Y_DCBits[13]	Y_DCBits[12]	
0x010	Y_DCValue[3]	Y_DCValue[2]	Y_DCValue[1]	Y_DCValue[0]	Luminance DC HuffValue
...	...	...	...	...	
0x018	Y_DCValue[11]	Y_DCValue[10]	Y_DCValue[9]	Y_DCValue[8]	
0x01C	0	0	0	0	
0x020	Y_ACBits[3]	Y_ACBits[2]	Y_ACBits[1]	Y_ACBits[0]	Luminance AC BitLength
...	...	...	...	...	
0x02C	Y_ACBits[15]	Y_ACBits[14]	Y_ACBits[13]	Y_ACBits[12]	
0x030	Y_ACValue[3]	Y_ACValue[2]	Y_ACValue[1]	Y_ACValue[0]	Luminance AC HuffValue
...	...	...	...	...	
0x0D0	0	0	Y_ACValue[161]	Y_ACValue[160]	
0x0D4	0	0	0	0	
0x0D8	C_DCBits[3]	C_DCBits[2]	C_DCBits[1]	C_DCBits[0]	Chrominance DC BitLength
...	...	...	...	...	
0x0E4	C_DCBits[15]	C_DCBits[14]	C_DCBits[13]	C_DCBits[12]	
0x0E8	C_DCValue[3]	C_DCValue[2]	C_DCValue[1]	C_DCValue[0]	Chrominance DC HuffValue
...	...	...	...	...	
0x0F0	C_DCValue[11]	C_DCValue[10]	C_DCValue[9]	C_DCValue[8]	
0x0F4	0	0	0	0	
0x0F8	C_ACBits[3]	C_ACBits[2]	C_ACBits[1]	C_ACBits[0]	Chrominance AC BitLength
...	...	...	...	...	
0x104	C_ACBits[15]	C_ACBits[14]	C_ACBits[13]	C_ACBits[12]	
0x108	C_ACValue[3]	C_ACValue[2]	C_ACValue[1]	C_ACValue[0]	Chrominance AC HuffValue
...	...	...	...	...	
0x1A8	0	0	C_ACValue[161]	C_ACValue[160]	

**mjpg\_qMatTable** Variable representing a pointer to an address in the Q-Matrix. The Q-Matrix coefficients are saved in pre-defined formats shown in [Table 4](#).

**Table 4. Q Matrix Format**

Offset Address	0	1	2	3	Description
0x000	Y_QMat[3]	Y_QMat[2]	Y_QMat[1]	Y_QMat[0]	Luminance Q Matrix
...	...	...	...	...	
0x03C	Y_QMat[63]	Y_QMat[62]	Y_QMat[61]	Y_QMat[60]	
0x040	C_BQMat[3]	C_BQMat[2]	C_BQMat[1]	C_BQMat[0]	Chrominance Q Matrix for Cb
...	...	...	...	...	
0x07C	C_BQMat[63]	C_BQMat[62]	C_BQMat[61]	C_BQMat[60]	
0x080	C_RQMat[3]	C_RQMat[2]	C_RQMat[1]	C_RQMat[0]	Chrominance Q Matrix for Cr
...	...	...	...	...	
0x0BC	C_RQMat[63]	C_RQMat[62]	C_RQMat[61]	C_RQMat[60]	

### 3.2.2.9 EncSliceMode

```
typedef struct {
    int sliceMode;
    int sliceSizeMode;
    int sliceSize;
} EncSliceMode;
```

#### Description

Structure used for declaring encoder slice mode and its options. This structure value is ignored for a MJPEG encoder.

**sliceMode** 0 = One slice per picture, 1 = Multiple slices per picture.  
If sliceMode is set to 1, in normal MPEG-4 mode, the resync-marker and packet header are inserted between the slice boundaries. In short video header with Annex K = 0, the GOB header is inserted at every GOB layer start. In short video header with Annex K = 1, multiple slices are generated. In AVC mode, multiple slice layer RBSP is generated. If sliceMode is set to 0, no corresponding information is generated for each encoder.

**sliceSizeMode** Size of a generated slice when sliceMode = 1, 0 means sliceSize is define by amount of bits, and 1 means sliceSize is defined by the number of Mbytes in a slice. This parameter is ignored when sliceMode = 0 or in short video header mode with Annex K = 0.

**sliceSize** Size of a slice in bits or Mbytes specified by sliceSizeMode. This parameter is ignored when sliceMode = 0 or in short video header mode with Annex K = 0.

### 3.2.2.10 EncOpenParam

```
typedef struct {
    CodStd bitstreamFormat;
    PhysicalAddress bitstreamBuffer;
    Uint32 bitstreamBufferSize;
    Uint8 *virt_bitstreamBuffer;
    int picWidth;
    int picHeight;
    Uint32 frameRateInfo;
    int bitRate;
    int initialDelay;
    int vbvBufferSize;
    int enableAutoSkip;
    int gopSize;
    EncSliceMode slicemode;
    int intraRefresh;
    int rcIntraQp;
    int dynamicAllocEnable;
    int ringBufferEnable;
    int interleavedCbCr;
    union {
        EncMp4Param mp4Param;
        EncH263Param h263Param;
        EncAvcParam avcParam;
        EncMjpgParam mjpgParam;
    } EncStdParam;
    int userQpMax;
    Uint32 userGamma;
    int RcIntervalMode;
    int MbInterval;
} EncOpenParam;
```

#### Description

Data structure for parameters when an encoder instance is opened

bitstreamFormat	Standard type of bitstream in encoder operation: STD_MPEG4, STD_H263, STD_AVC or STD_MJPG, as defined in <a href="#">Section 3.2.1.5, “CodStd.”</a>
bitstreamBuffer	Start address of bit stream buffer into which encoder places the bitstream. This address must be 4 byte-aligned.
bitstreamBufferSize	Size in bytes of a buffer pointed to by bitstreamBuffer. This value must be a multiple of 1024. The maximum size is 16383×1024 bytes.
virt_bitstreamBuffer	Virtual start address of the bit stream buffer where the encoder places bit streams. This virtual address corresponds to the physical address of bitstreamBuffer.
picWidth	Width of a picture to be encoded in pixels
picHeight	Height of a picture to be encoded in pixels
frameRateInfo	The 16 least significant bits, [15:0], is a numerator and 16 most significant bits, [31:16], is a denominator for calculating the frame rate. The numerator is clock ticks per second, and the denominator is clock ticks between frames minus 1. The frame rate can be defined by $(\text{frameRateInfo} \& 0\text{xffff}) / ((\text{frameRateInfo} \gg 16) + 1)$ .

For example, a `frameRateInfo` value of 30 represents 30 frames/sec, and the value 0x3e87530 represents 29.97 frames/sec.

This value is meaningless for H.264 because the frame rate is determined by the container. So the frame rate of an encoded stream may be different from `frameRateInfo`.

<code>bitRate</code>	Target bit rate in kbps. If 0, there is no rate control and pictures are encoded with a quantization parameter equal to <code>quantParam</code> in <code>EncParam</code> .
<code>initialDelay</code>	Time delay (in ms) for the bit stream to reach initial occupancy of the vbv buffer from zero level. This value is ignored if rate control is disabled. The value 0 means the encoder does not check for reference decoder buffer delay constraints.
<code>vbvBufferSize</code>	<code>vbv_buffer_size</code> in bits. This value is ignored if rate control is disabled or <code>initialDelay</code> is 0. The value 0 means the encoder does not check for reference decoder buffer size constraints.
<code>enableAutoSkip</code>	0 = automatic skip disabled, 1 = automatic skip enabled. Automatic skip is when the encoder skips frame encoding when generated bitstream so far is too big considering the target bitrate. This parameter is ignored if rate control is not used ( <code>bitRate</code> = 0).
<code>gopSize</code>	GOP size. 0 = only first picture is I, 1 = all I pictures, 2 = IPIP, 3 = IPPIPP, and so on. The maximum value is 32,767, but in practice, a smaller value should be chosen by the application for proper error concealment. This value is ignored for <code>STD_MJPG</code> .
<code>slicemode</code>	Parameter for slice mode
<code>intraRefresh</code>	0 = Intra MB refresh is not used. Otherwise = at least <i>N</i> MBs in every P-frame are encoded as intra MBs. This value is ignored in for <code>STD_MJPG</code> .
<code>rcIntraQp</code>	Quantization parameter for I frame. The allowed values are -1 or corresponding available range. When this value is -1, the quantization parameter for I frames is automatically determined by the VPU. In MPEG4/H.263 mode, the range is 1-31; in H.264 mode, the range is from 0-51. This is ignored for <code>STD_MJPG</code> .
<code>dynamicAllocEnable</code>	0 = disable, 1 = enable When this field is set, dynamic buffer allocation is enabled under buffer reset mode for encoder operation, so that the buffer start address specified in the <code>EncOpenParam</code> , <code>bitstreamBuffer</code> , is ignored in picture encoding. In this case, the picture buffer start address should be specified in the <code>EncParam</code> , <code>picStreamBufferAddr</code> , at every call of <code>vpu_EncStartOneFrame()</code> . When this field is not set, the picture buffer start address given by <code>bitstreamBuffer</code> , is used for encoder operations, even though buffer reset mode is enabled.
<code>ringBufferEnable</code>	0 = disable, 1 = enable This flag enables the streaming mode for the current encoder instance. Two streaming modes, packet-based streaming with ring-buffer (buffer-reset mode) and frame-based streaming with line buffer (buffer-flush mode) can be configured using this flag.

	When this field is set, packet-based streaming with ring-buffer is used. When this field is not set, frame-based streaming with line-buffer is used.
interleavedCbCr	0 = non-interleaved chroma YUV input format that the CbCr data is inputted into separate frame buffers. 1 = interleaved chroma YUV input format that the CbCr data is inputted into one chroma buffer. For interleaved Cb/Cr map, the base address for the Cr is ignored because the base address for the Cb is used to store or load the interleaved Cb/Cr samples.
mp4Param	Parameters for MPEG-4 part 2 Visual
h263Param	Parameters for ITU-T H.263
avcParam	Parameters for AVC
mjpgParam	Parameters for MJPEG
userQpMax	Sets the maximum quantized step parameter for encoding. 0 = disables this setting and the VPU uses the default maximum quantized step depending on the mode. For MPEG-4/H.263, the allowed maximum value is 31, so the available values are from 1 to 31. In H.264 mode, the allowed maximum value is 51, so the available values are from 1 to 51.
userGamma	Smoothing factor in the estimation. A value for gamma is factor×32768, where the value for factor must be between 0 and 1. If the smoothing factor is close to 0, Qp changes slowly. If the smoothing factor is close to 1, Qp changes quickly. The default Gamma value is 0.75×32768.
RcIntervalMode	Encoder rate control mode setting. The host sets the bitrate control mode according to the required case. The default value is 1. 0 = normal mode rate control 1 = FRAME_LEVEL rate control 2 = SLICE_LEVEL rate control 3 = USER DEFINED MB LEVEL rate control
MbInterval	User defined Mbyte interval value. The default value is 2 macroblock rows. For example, if the resolution is 720×470, then the two macroblock row is $2 \times (720/16) = 90$ . This value is used only when the RcIntervalMode is 3.

### 3.2.2.11 EncReportBufSize

```
typedef struct {
    int mbInfoBufSize;
    int mvInfoBufSize;
    int sliceInfoBufSize;
} EncReportBufSize;
```

#### Description

Data structure for returning the size of the buffer to save the corresponding report information. The buffer must be allocated with the size for the specific information to enable the report. For example, if the host application wants to get the MB information of the current encoding, **vpu\_EncGetInitialInfo()** returns the necessary buffer size. Then host application must allocate a virtual buffer of this size and call

**vpu\_EncGiveCommand()** with the ENC\_SET\_REPORT\_MBINFO command to register the base address of the allocated virtual buffer. The driver saves the reported information into this buffer.

<b>mbInfoBufSize</b>	Buffer size for MB information
<b>mvInfoBufSize</b>	Buffer size for motion vector information
<b>sliceInfoBufSize</b>	Buffer size for slice information

### 3.2.2.12 EncInitialInfo

```
typedef struct {
    int minFrameBufferCount;
    EncReportBufSize reportBufSize;
} EncInitialInfo;
```

#### Description

Data structure for parameters of **vpu\_EncGetInitialInfo()** which are needed for the minimum required buffer count in host applications and the necessary size of the buffers that are used to save the corresponding information. This returned value is used to allocate frame buffers in **vpu\_EncRegisterFrameBuffer()**.

<b>minFrameBufferCount</b>	Minimum required buffer count in host applications. This returned value is used to allocate frame buffers in <b>vpu_EncRegisterFrameBuffer()</b>
<b>reportBufSize</b>	Data report requested buffer size information

### 3.2.2.13 EncParam

```
typedef struct {
    FrameBuffer * sourceFrame;
    int forceIPicture;
    int skipPicture;
    int quantParam;
    PhysicalAddress picStreamBufferAddr;
    int picStreamBufferSize;
} EncParam;
```

#### Description

Data structure for configuring one frame encoding

<b>sourceFrame</b>	Frame buffer containing source image to be encoded
<b>forceIPicture</b>	<p>If this value is 0, the picture type is determined by the VPU according to the various parameters such as encoded frame number and GOP size.</p> <p>If this value is 1, the frame is encoded as an I-picture regardless of the frame number or GOP size, and I-picture period calculation is reset to the initial state. For MPEG-4 and H.263, I-picture is sufficient for decoder refresh. For H.264 mode, the picture is encoded as an Instantaneous Decoding Refresh (IDR) picture. This value is ignored if skipPicture = 1.</p>
<b>skipPicture</b>	<p>If this value is 0, the encoder encodes the picture as normal.</p> <p>If this value is 1, the encoder ignores sourceFrame and generates a skipped</p>

	picture. In this case, the reconstructed image is a duplication of the previous picture. The skipped picture is encoded as P-type regardless of GOP size.
quantParam	This value is used for all quantization parameters in case of VBR (no rate control). The range of value is 1–31 for MPEG-4 and 0–51 for H.264. When rate control is enabled, this field is ignored.
picStreamBufferAddr	Start address of a picture stream buffer under line-buffer mode and dynamic buffer allocation. This variable represents the start of a picture stream for encoded output. In buffer-reset mode, an application might use multiple picture stream buffers for the best performance. Using this variable, an application re-registers the start position of the picture stream while issuing a picture encoding operation. This start address of this buffer must be 8-byte aligned, and its size is specified by picStreamBufferSize. In packet-based streaming with ring-buffer, this variable is ignored. This variable is only meaningful when both line-buffer mode and dynamic buffer allocation are enabled.
picStreamBufferSize	Byte size of a picture stream chunk. This variable represents byte size of a picture stream buffer and is crucial in line-buffer mode because encoder output can be corrupted if this size is smaller than any picture encoded output. Therefore, this value should be big enough for storing multiple picture streams with average size. In packet-based streaming with ring-buffer, this variable is ignored. This variable specifies the picture stream buffer size for encoded output in line-buffer mode.

### 3.2.2.14 EncOutputInfo

```
typedef struct {
    PhysicalAddress bitstreamBuffer;
    Uint32 bitstreamSize;
    int bitstreamWrapAround;
    int picType;
    int numOfSlices;
    ReportInfo mbInfo;
    ReportInfo mvInfo;
    ReportInfo sliceInfo;
} EncOutputInfo;
```

#### Description

Data structure for reporting the results of picture encoding operations

bitstreamBuffer	Physical address of the starting point of a newly encoded picture stream. If dynamic buffer allocation is enabled in line-buffer mode, this value is identical to the picture stream buffer address specified by the host application.
bitstreamSize	Byte size of the encoded bitstream
bitstreamWrapAround	Flag for bitstream buffer wrap-around. If this flag is set a larger buffer is required.
picType	Coded picture type. In H.263 and MPEG4, 0 = I picture, and 1 = P picture. In AVC, 0 = IDR picture and 1 = Non-IDR picture.
numOfSlices	Number of slices included in a newly encoded picture. When sliceReport in EncOpenParam is 0, this value is invalid.

mbInfo	Parameter to save the MB reporting
mvInfo	Parameter to save the MV reporting
sliceInfo	Parameter to save the slice reporting

### 3.2.2.15 SearchRamParam

```
typedef struct {
    PhysicalAddress searchRamAddr;
    int SearchRamSize;
} SearchRamParam;
```

#### Description

Structure used when host processor sets ME search RAM start address. SearchRamSize is calculated by:  
 $\text{SearchRamSize} = ((\text{picWidth} + 15) \& \sim 15) \times 36 + 2048$

This amount of memory space should be reserved by the host application for ME operations.

### 3.2.2.16 DecParamSet

```
typedef struct {
    Uint32 * paraSet;
    int sizeInByte;
} DecParamSet;
```

#### Description

Structure used when the host processor requires to send SPS data or PPS data. paraSet is the base address of the buffer that contains the SPS and/or SPS data. The buffer size should be adjusted to a multiple of 8 bytes before being passed to the API, so sizeInByte is the real size of the SPS and/or PPS data. The SPS data or PPS data is used in real applications as a type of out-of-band information.

### 3.2.2.17 DecOpenParam

```
typedef struct {
    CodStd bitstreamFormat;
    PhysicalAddress bitstreamBuffer;
    Uint8 *virt_bitstreamBuffer;
    int bitstreamBufferSize;
    int mp4DeblkEnable;
    int reorderEnable;
    int filePlayEnable;
    int picWidth;
    int picHeight;
    int dynamicAllocEnable;
    int streamStartByteOffset;
    int mjpg_thumbNailDecEnable;
    PhysicalAddress psSaveBuffer;
    int psSaveBufferSize;
    int interleavedCbCr;
    int mp4Class;
} DecOpenParam;
```

## Description

Data structure used to open a new decoder instance

bitstreamFormat	Standard type of bitstream decoder operation as defined in <a href="#">Section 3.2.1.5</a> , “CodStd.”
bitstreamBuffer	Start physical address of the bit stream buffer from which the decoder retrieves the next bitstream. This address must be 8 byte-aligned. This variable is not valid in file-play mode with dynamic buffer allocation because, the bitstream buffer is dynamically re-allocated for multiple buffering.
virt_bitstreamBuffer	Start virtual address of the bit stream buffer from which the decoder can retrieve the next bitstream. The virtual address corresponds to physical address of bitstreamBuffer.
bitstreamBufferSize	Size in bytes of a buffer pointed to by bitstreamBuffer. This value must be a multiple of 1024. The maximum size is 16383×1024 bytes. This variable is not valid in file-play mode with dynamic buffer allocation because in this case, the bitstream buffer size is specified by the variable chunkSize.
mp4DbkEnable	0 = disable, 1 = enable When this field is set in MPEG4 and H.263 (post-processing) modes, the decoder applies MPEG-4 deblocking filter output to the host application.
reorderEnable	1 = enables display buffer reordering when decoding H.264 streams. In H.264 mode, the output decoded picture is re-ordered if pic_order_cnt_type is 0 or 1 and the decoder must delay the output display for re-ordering. However, some applications (such as video telephony) do not require such display delay. The host may set this flag to 0 to disable output display buffer reordering. Then the BIT processor does not re-order the output buffer when pic_order_cnt_type is 0 or 1. If pic_order_cnt_type is 2 or in MPEG4 or H.263 modes, this flag is ignored because output display buffer reordering is not allowed.
filePlayEnable	0 = disable, 1 = enable and file-play mode is enabled for decoder operations. File-play mode means applications provide the chunk size and reset the write pointer at each frame processing.
picWidth	Horizontal picture size read from the file format header used for codecs for which the picture size is not available in the bitstream, for example Divx3.11.
picHeight	Vertical picture size read from the file format header used for codecs for which the picture size is not available in the bitstream, for example Divx3.11.
dynamicBuffAllocEnable	1 = dynamic buffer allocation enabled under file-play mode for decoder operations. When enabled, the buffer start address specified in bitstreamBuffer is ignored in decoder operations and the picture buffer start address is specified in DecParam: picStreamBufferAddr, at every call of <b>vpu_DecStartOneFrame</b> .

	0 = disable, picture buffer start address given by bitstreamBuffer is used in decoder operation, even though file-play mode is enabled.
streamStartByteOffset	Start byte offset of the stream buffer. Since the VPU has an internal limitation that the stream buffer start address must be 8-byte aligned, the host application may be required to copy the stream data to an 8-byte aligned buffer. This offset allows this overhead to be saved. This offset should be between 0 and 7.
mjpg_thumbNailDecEnable	0 = disable, 1 = enable and the MJPEG decoder decodes a thumbnail image. This variable is only valid in STD_MJPEG mode.
psSaveBuffer	Start address of the PS (SPS/PPS) save buffer which the decoder saves PS (SPS/PPS) RBSP. This address must be 8 byte-aligned. This variable is only valid for H.264 decoder mode.
psSaveBufferSize	Size in bytes of a buffer pointed to by psSaveBuffer. This value must be a multiple of 1024. The maximum size is 65565×1024 bytes. This variable is only valid when decoding H.264 streams.
interleavedCbCr	0 = non-interleaved chroma output format where the CbCr data is written into separate frame buffers. 1 = interleaved chroma output format where the CbCr data is written into one chroma buffer. For interleaved mode, the base address for the Cr is meaningless because the base address for the Cb is used to store or load the interleaved Cb/Cr samples.
mp4Class	Parameter used to distinguish the subclass of MPEG4: 0 = MPEG-4; 1 = DivX 5.0 or higher; 2 = Xvid; 5 = DivX 4.0 This variable is only valid when decoding an MPEG-4 stream. The VPU regards MPEG4, Divx4 and Divx higher, Xvid as same codec. If the upstream processing does not tell the exact subclass type, use MPEG-4, but it is highly encouraged to set the correct subclass type.

### 3.2.2.18 DecReportBufSize

```
typedef struct {
    int mbInfoBufSize;
    int mvInfoBufSize;
    int frameBufStatBufSize;
    int userDataBufSize;
} DecReportBufSize;
```

#### Description

Data structure for returning the size of the buffer to save the corresponding report information. This buffer must be allocated with the return size for the specific information to enable the report. For example, if the host application requires the MB information of the current encoding, **vpu\_DecGetInitialInfo** returns the necessary buffer size. Then the host application allocates a virtual buffer with this size and calls **vpu\_DecGiveCommand** with the DEC\_SET\_REPORT\_MBINFO command to register the base address of the allocated virtual buffer. The driver saves the reported information into this buffer.

mbInfoBufSize            Buffer size for Mb information

mvInfoBufSize	Buffer size for motion vector information
frameBufStatBufSize	Buffer size for current frame buffer status
userDataBufSize	Buffer size for decoded user data

### 3.2.2.19 DecInitialInfo

```
typedef struct {
    int picWidth;
    int picHeight;
    Uint32 frameRateInfo;
    Uint32 picCropEnable;
    Rect picCropRect;
    int mp4_dataPartitionEnable;
    int mp4_reversibleVlcEnable;
    int mp4_shortVideoHeader;
    int h263_annexJEnable;
    int minFrameBufferCount;
    int frameBufDelay;
    int normalSliceSize;
    int worstSliceSize;
    int mjpg_thumbNailEnable;
    int mjpg_sourceFormat;
    int profile;
    int level;
    int interlace;
    int direct8x8Flag;
    int vcl_psf;
    int aspectRateInfo;
    int constraint_set_flag[4];
    DecReportBufSize reportBufSize;
} DecInitialInfo;
```

#### Description

Data structure to get information necessary to start decoding

picWidth	Horizontal picture size in pixels. This width value is used when allocating decoder frame buffers. In some cases, this returned value, the display picture width declared on the stream header, should be modified before allocating the frame buffers. When the picture width is not a multiple of 16, the picture width for buffer allocation should be re-calculated from the declared display width as: $\text{picBufWidth} = ((\text{picWidth} + 15)/16) \times 16,$ where picBufWidth is the horizontal picture buffer width. When picWidth is a multiple of 16, picWidth = picBufWidth.
picHeight	Vertical picture size in pixels. This height value is used when allocating decoder frame buffers. In some cases, this returned value, the display picture height declared on the stream header, should be modified before allocating the frame buffers. When the picture height is not a multiple of 16, the picture height for buffer allocation should be re-calculated from the declared display height as: $\text{picBufHeight} = ((\text{picHeight} + 15)/16) \times 16,$

	where picBufHeight is the vertical picture buffer height. When picHeight is a multiple of 16, picHeight = picBufHeight.
frameRateInfo	The 16 least significant bits, [15:0] is a numerator and 16 most significant bits [31:16], is a denominator for calculating the frame rate. The numerator is the clock ticks per second, and the denominator is the clock ticks between frames minus 1. So the frame rate can be defined by $(\text{numerator}/(\text{denominator} + 1))$ , which equals to $(\text{frameRateInfo} \& 0xffff) / ((\text{frameRateInfo} \gg 16) + 1)$ . For example, the value of 30 for frameRateInfo represents 30 frames/sec, and the value of 0x3e87530 represents 29.97 frames/sec.
picCropEnable	Indicates if picCropRect is valid. If picCropEnable = 0, the picCropRect should be ignored. picCropEnable = 1, there is cropping rectangle information picCropRect.
picCropRect	Picture cropping rectangle information. If picCropEnable = 0, this field is invalid. This structure specifies the cropping rectangle information only for a H.264 decoder. The size and position of the cropping window in a full frame buffer is presented in this structure. This structure is only valid for H.264 decoder mode.
mp4_dataPartitionEnable	0 = disable, 1 = enable
mp4_reversibleVlcEnable	0 = disable, 1 = enable
mp4_shortVideoHeader	0 = disable, 1 = enable
H263_annexJEnable	0 = disable, 1 = enable
minFrameBufferCount	Minimum number of frame buffers required for decoding. The application must allocate at least this number of frame buffers and register those number of buffers to the VPU using <b>vpu_DecRegisterFrameBuffer()</b> before decoding pictures.
frameBufDelay	Maximum display frame buffer delay for buffering decoded picture reorder. The VPU may delay decoded picture displays for display reordering H.264 mode, when pic_order_cnt_type is 0 or 1 and for B-frame handling in VC-1 decoder. (By default, some H.264 encoder set pic_order_cnt_type to 0 or 1, but in BP applications, this setting is not actually used in practice.)
normalSliceSize	Recommended size of buffer to save slice in normal case. This value is determined by a quarter of the memory size of one raw YUV image in Kbytes.
worstSliceSize	Recommended size of buffer used to save slice in worst case. This value is determined by half of the memory size for one raw YUV image in Kbytes.
mjpg_thumbNailEnable	0 = disable, 1 = enable and the stream which is decoded as thumbnail.
mjpg_sourceFormat	The chroma format of encoded image of the stream. The format defines the chrominance size of the source image and can be a value between 0 and 4. 0 = 4:2:0, 1 = 4:2:2 horizontal, 2 = 4:2:2 vertical, 3 = 4:4:4, 4 = 4:0:0

profile	<p>Profile of decoded stream and used as follows.</p> <p>H.264—profile_idc</p> <p>Vc1—0–2 (SMTPE reserved), 3 (advanced profile)</p> <p>MP2—3'b101: Simple, 3'b100: Main, 3'b011: SNR Scalable, 3'b10: Spatially Scalable, 3'b001: High</p> <p>MP4—8'b00000000: SP, 8'b00010001: ASP Real Video: 8 (version 8), 9 (version 9), 10 (version 10)</p>
level	<p>Level of decoded stream and used as follows.</p> <p>H.264—level_idc</p> <p>Vc1—level</p> <p>MP2—4'b1010: Low, 4'b1000: Main, 4'b0110: High 1440, 4'b0100: High</p> <p>MP4—4'b0000: L0, 4'b0001: L1, 4'b0010: L2, 4'b0011: L3, and so on</p> <p>Real Video—N/A (real video does not have level information)</p>
interlace	<p>1 = decoded stream may be decoded into progressive or interlace frame</p> <p>Otherwise, decoded stream is progressive frame</p>
Direct8x8Flag	Direct_8x8_inference_flag in H.264 SPS
vc1_psf	Only available in VC1 mode and indicates the value of the progressive segmented frame
aspectRateInfo	<p>0 = aspect ratio information is not present.</p> <p>[H.264]—if aspectRateInfo [31:16] is 0, aspectRateInfo [7:0] is aspect_ratio_idc. Otherwise, AspectRatio is Extended_SAR.</p> <p>sar_width = aspectRateInfo [31:16]</p> <p>sar_height = aspectRateInfo [15:0]</p> <p>[VC-1]—Aspect Width = aspectRateInfo [31:16],</p> <p>Aspect Height = aspectRateInfo [15:0]</p> <p>[MP4]—This value is index of Table 6-12 in ISO/IEC 14496-2</p> <p>[MP2]—This value is index of Table 6-3 in ISO/IEC 13818-2 This value is determined by half of the memory size for one raw YUV image in Kbytes.</p>
Constraint_set_flag	Syntax element in H.264 used to make level. Ignored in other standards.

### 3.2.2.20 DecAvcSliceBufInfo

```
typedef struct {
    PhysicalAddress sliceSaveBuffer;
    int sliceSaveBufferSize;
} DecAvcSliceBufInfo;
```

#### Description

Data structure used when host application transfers H.264 decoder slice save buffer information

sliceSaveBuffer	Start address of slice save buffer which the decoder can save slice RBSP. This address must be 8 byte-aligned. This variable is only valid for H.264 decoder.
sliceSaveBufferSize	Size in bytes of a buffer pointed by sliceSaveBuffer. This value must be a multiple of 1024. The maximum size is 65535×1024 bytes. This variable is only valid for H.264 decoder.

### 3.2.2.21 DecBufInfo

```
typedef struct {
    DecAvcSliceBufInfo avcSliceBufInfo;
} DecBufInfo;
```

#### Description

Data structure used when the host application transfers additional buffer information except frame buffer

**avcSliceBufInfo**      Start address and size of slice save buffer which the decoder can save slice RBSP.  
This variable is only valid for H.264 decoder.

### 3.2.2.22 DecParam

```
typedef struct {
    int prescanEnable;
    int prescanMode;
    int iframeSearchEnable;
    int skipframeMode;
    int skipframeNum;
    int chunkSize;
    int picStartByteOffset;
    PhysicalAddress picStreamBufferAddr;
} DecParam;
```

#### Description

Data structure for picture decoding options

prescanEnable	0 = disable, 1 = enable If this option is enabled, the decoder performs scanning stream buffers to check whether a full picture stream exists or not. If there is no full picture stream, decoding picture is not initiated. This option is provided to prevent the decoder from hanging. When multiple picture decoding is needed, for example, for the first picture decoding with display reordering enabled, pre-scan does not prevent decoder hanging. So in this cases, it is recommended to disable this option.
prescanMode	Operation mode of decoder after pre-scan detects a full picture stream 0 = Start decoding, 1 = Returns without decoding If this option is enabled, the decoder returns without picture decoding even though there is a full picture stream in the stream buffer. This option is provided for general usage of pre-scan option as a useful tool for stream buffer check.
iframeSearchEnable	0 = disable, 1 = enable and the decoder performs skipping frame decoding until decoder meets an I (IDR) frame. If there is no I frame in the stream, the decoder waits for a I (IDR) frame. If skipframeNum is n, the decoder seeks the (n + 1) <sup>th</sup> I (IDR) frame. When decoder meets an EOS (End Of Sequence) code during I-Search, the decoder returns -1 (0xFFFF). If this option is enabled, prescanEnable, prescanMode and skipframeMode options are ignored.
skipframeMode	Skip frame function enable and operation mode: 0 = skip frame disable 1 = skip frame enabled (skip frames but I (IDR) frame)

	2 = skip frame enabled (skip any frames) If this option enabled, the decoder skip decoding as many as skipframeNum frames. If skipframeNum is 1, the prescan function is enabled and prescanMode is 0. After the decoder skips frames, the decoder returns decoded index -2 (0xFFFE) when decoder does not have any frames displayed. When decoder meets EOS (End Of Sequence) code during frame skip, the decoder returns -1 (= 0xFFFF). If this option is enabled, prescanEnable and prescanMode options are ignored.
skipframeNum	Number of skip frames. If the iframeSearchEnable option is enabled, this number is the number of skipping I (IDR) frame. If the iframeSearchEnable option is disabled and the skipframeMode option is enabled, this number is the number of skipping frames. When this number is 0, the skipframeMode option is disabled.
picStartByteOffset	Start byte offset of the picture stream buffer. Since the VPU has an internal limitation that stream buffer start address must be 4-byte aligned, the host may be required to copy the stream data to a separate 8-byte aligned buffer. This offset allows this overhead to be saved. This offset should be between 0 and 3.
chunkSize	Byte size of a picture stream to be decoded. This variable represents the byte size of a picture stream, and can be read from file container header field. This variable is crucial in file-play mode operation. In packet-based streaming with ring-buffer, this variable is ignored. When this number is 0, skipframeMode option is disabled.
picStreamBufferAddr	Physical address of the start address of the picture stream buffer in file-play mode This variable represents the start of a picture stream to be decoded. In file-play mode, the application might use multiple picture stream buffers for the best performance. Using this variable, the application can re-register the start position of the picture stream while issuing a picture decoding operation. The start address of this buffer must be 8-byte aligned, and its size is specified in the variable, chunkSize. This variable is only meaningful when both file-play mode and dynamic buffer allocation are enabled.

### 3.2.2.23 DecOutputInfo

```
typedef struct {
    int indexFrameDisplay;
    int indexFrameDecoded;
    int picType;
    int numOfErrMBs;
    int hScaleFlag;
    int vScaleFlag;
    int prescanresult;
    int notSufficientPsBuffer;
    int notSufficientSliceBuffer;
    int decodingSuccess;
    int interlacedFrame;
    int mp4PackedPBframe;
    int h264Npf;
    int pictureStructure;
    int topFieldFirst;
    int repeatFirstField;
    union {
```

```

        int mp2_progressiveFrame;
        int vc1_repeatFrame;
    };
    int fieldSequence;
    ReportInfo mbInfo;
    ReportInfo mvInfo;
    ReportInfo frameBufStat;
    ReportInfo userData;
    int decPicHeight;
    int decPicWidth;
    Rect decPicCrop;
} DecOutputInfo;

```

## Description

Data structure to get information resulting from decoding a frame

indexFrameDisplay	Frame buffer index of a picture to be displayed among frame buffers which were registered using <b>vpu_DecRegisterFrameBuffer()</b> . Frame data to be displayed is stored into the frame buffer specified by this index. When a delay in display does not exist, this index always is the same as indexFrameDecoded. But if not, (for example, display reordering in AVC or B-frames in VC-1), this index is not the same value with indexFrameDecoded. If the decoder cannot provide a display output at the beginning of sequence decoding with different display order, this index always has -2 (0xFFFE) or -3 (0xFFFD) depending on the decoder skip option. And at the end of sequence decoding, if there is no more output for display, this value has -1 (0xFFFF). By checking this index, the host application can easily know whether sequence decoding has finished or not.
indexFrameDecoded	Frame buffer index of decoded picture among frame buffers which were registered using <b>vpu_DecRegisterFrameBuffer()</b> . A decoded frame during current picture decoding operation is stored into the frame buffer specified by this index. If decoder meets EOS or skip, the decoder return -1 (0xFFFF) to represent that no decoded output is generated. -2 means no real decoding operation due to meeting a header error. Because of delays in display, the return value of -1 does not mean end of decoding. In order to check the end of decoding, the host application should refer to indexFrameDisplay.
picType	<p>Picture type of the current decoded picture. This value has different meaning in different codec standard.</p> <p>For VC1 SP/MP: 0 = I picture, 1 = P picture, 2 = BI picture, 3 = B picture, 4 = SKIPPED picture.</p> <p>In VC1 AP interlacing, picType contains two fields picture type information. Bit[2:0] is for the second field, and bit[5:3] is for first field. The respective value has same meaning as SP/MP case described above. For example, 0 - 000_000: both first and second field are I picture and 1 - 000_001: first field is I picture and second field is P picture.</p> <p>In other codec cases: 0 = I picture, 1 = P picture, 2 = B picture</p>
numOfErrMBs	Number of erroneous macroblocks while decoding a picture

hScaleFlag	Flag for reduced resolution output in horizontal direction. For VC1 decoding, the resulting picture width from the decoder may be half the decoded picture width. In this case, this flag is set, and the host application should scale up the picture by two times in the horizontal direction to get proper display output.
vScaleFlag	Flag for reduced resolution output in vertical direction. For VC1 decoding, the resulting picture height from the decoder may be half the decoded picture height. In this case, this flag is set, and the host application should scale up this picture by two times in the vertical direction to get proper display output.
prescanResult	0 = incomplete picture stream, 1 = full picture stream exists, 2 = pre-scan disabled If the application enables pre-scan mode for running a picture decoding task, then it should check this flag first. If this flag is equal to 0, all the other output information has no meaning and the application should ignore all output information. Only if prescanResult is greater than 0 is the other output information meaningful for the application.
notSufficientPsBuffer	Flag that represents whether PS (SPS/PPS) save buffer is sufficient to decode the current picture. The VPU does not get the last part of the current picture stream because of buffer overflow. The host must close the current instance because the picture streams cannot be decoded properly because of loss of SPS/PPS data.
notSufficientSliceBuffer	Flag that represents whether slice save buffer is sufficient to decode the current picture. The VPU does not get the last part of the current picture stream, and macroblock errors are issues because of buffer overflow. The host can continue decoding the remaining pictures of the current input stream without closing the current instance, even though several pictures can be error-corrupted.
decodingSuccess	0 = incomplete finish of decoding process, = complete finish of decoding process This variable means that the decoding process is finished completely. If stream has errors in the picture header syntax or the first slice header syntax of H.264 stream, The VPU does not initiate the MB decoding routine and returns immediately. In this case, the VPU returns 0 which means incomplete finish of decoding process.
interlacedFrame	0 = progressive frame which consists of one frame picture 1 = interlaced frame which consists of two field picture (top field and bottom field); This variable indicates that the frame is the interlaced frame. If this value is set, the host application may use a de-interlacing filter to enhance image quality.
mp4PackedPBframe	0 = normal frame chunk data, 1 = packed PB frame chunk data. This variable indicates that the frame chunk data is a packed PB frame chunk. If this value is set, the host application must re-use this chunk in the next decoding command. This variable is only valid for MPEG-4 file-play mode.
h264Npf	When a Non-Paired Field (NPF) occurs in the display picture, this flag indicate that a top or bottom field is absent.

	0 = no NPF 1 = only bottom field of picture is absent 2 = only top field of picture is absent 3 = all field (top/bottom) of picture is absent
pictureStructure	Variable that indicates whether that the decoded picture is progressive or interlaced picture. The value of pictureStructure is used as below. H.264—FieldPicFlag, Vc1—FCM (Progressive 0, 2 Frame interlace, 3 Field interlaced) MP2—picture structure (TopField: 1, BotField: 2, Frame: 3) MP4—N/A Real Video—N/A
topFieldFirst	When the decoded picture is a field picture, if this value is 1, the top field is decoded first, then the bottom field is decoded. If this value is 0, the decoding order is bottom field first and then the top field. The topFieldFirst is used by the post processing for de-interlacing.
repeatFirstField	Variable that means repeat first field is used during the display process
mp2_progressiveFrame	Variable used to indicate progressive_frame in picture coding extension in MP2
vc1_repeatFrame	For VC1, this variable means RPTFRM (Repeat Frame Count) is used during the display process
fieldSequence	Variable used to indicate field_sequence in picture coding extension in MP2
mbInfo	Parameter to save the MB reporting if enabling the MB information reporting
mvInfo	Parameter to save the MV reporting if enabling the MV information reporting
frameBufStat	Parameter to save the current frame buffer status information if the frame buffer status reporting is enabled
userData	Parameter to save the decoded user data if the user data reporting is enabled
decPicHeight	Picture height in the pixel of the frame with the index of indexFrameDisplay. So host application needs to use this information in the case that the decoded stream has changed resolution.
decPicWidth	Picture height of the frame with the index of indexFrameDisplay. For MJPEG decoding, decPicHeight and decPicWidth are the size of the decoded rotator frame saved in the rotation frame buffer registered by the SET_ROTATOR_OUTPUT command. The VPU supports the changed resolution decoding. The VPU only supports the changed resolution not larger than the original size. For example, the changed sequence of VGA > QVGA > VGA is supported
decPicCrop	Cropping information for H.264 changed resolution decoding. This parameter is valid only for H.264.

### 3.2.2.24 VPUMemAlloc

```
typedef struct {
    ULONG PhysAdd;
    ULONG VirtAdd;
    UINT Reserved;
} VPUMemAlloc;
```

#### Description

Data structure used when the host application allocates physically continuous memory for the VPU

PhysAdd	Physical base address of the buffer allocated by driver if allocating successfully
VirtAdd	Virtual base address corresponds to the PhysAdd that host application can access
Reserved	Used by driver internally

## 3.3 API Definitions

This section provides a description of the i.MX51 VPU API definitions.

### 3.3.1 Overview

This section provides an overview of the VPU API definitions. The basic API architecture is presented as well as the operation flow of both decoder and encoder based VPU API functions.

#### 3.3.1.1 Basic Architecture

The i.MX51 VPU API has the following three basic categories:

- Control API—API functions for general control of the VPU such as initialization
- Decoder API—API functions for VPU decoding operations
- Encoder API—API functions for VPU encoding operations

The i.MX51 VPU API functions are based on a frame-by-frame picture processing scheme. To run a picture decoder or encoder, the application calls a API function and after completion the processing, the application can check the results of the picture processing.

To support multi-instance decoding and encoding, the i.MX51 VPU API functions use a handle for specify a certain instance. The handle for each instance is provided when the application creates a new decoder or encoder instance. If the application wants to give a command to a specific instance, the corresponding handle is used in every API function call for that instance.

#### 3.3.1.2 Decoder Operation Flow

To decode a bitstream, the application completes the following steps:

1. Open a decoder instance using **vpu\_DecOpen()**
2. To provide the proper amount of bitstream, get the bitstream buffer address using **vpu\_DecGetBitstreamBuffer()**

3. After transferring the decoder input stream, inform the amount of bits transferred into the bitstream buffer using **vpu\_DecUpdateBitstreamBuffer()**
4. Before starting a picture decoder operation, get the crucial parameters for decoder operations such as picture size, frame rate, required frame buffer size using **vpu\_DecGetInitialInfo()**
5. Using the returned frame buffer requirement, allocate the proper size of the frame buffers and convey this data to the i.MX51 VPU using **vpu\_DecRegisterFrameBuffer()**
6. Start a picture decoder operation picture-by-picture using **vpu\_DecStartOneFrame()**
7. Wait for the completion of the picture decoder operation interrupt event
8. Check the results of the decoder operation using **vpu\_DecGetOutputInfo()**
9. After displaying  $n^{\text{th}}$  frame buffer, clear the buffer display flag using **vpu\_DecClrDispFlag()**
10. If there is more bitstream to decode, go to Step 6, otherwise go to the next step
11. Terminate the sequence operation by closing the instance using **vpu\_DecClose()**

The decoder operation flow is shown in Figure 4.

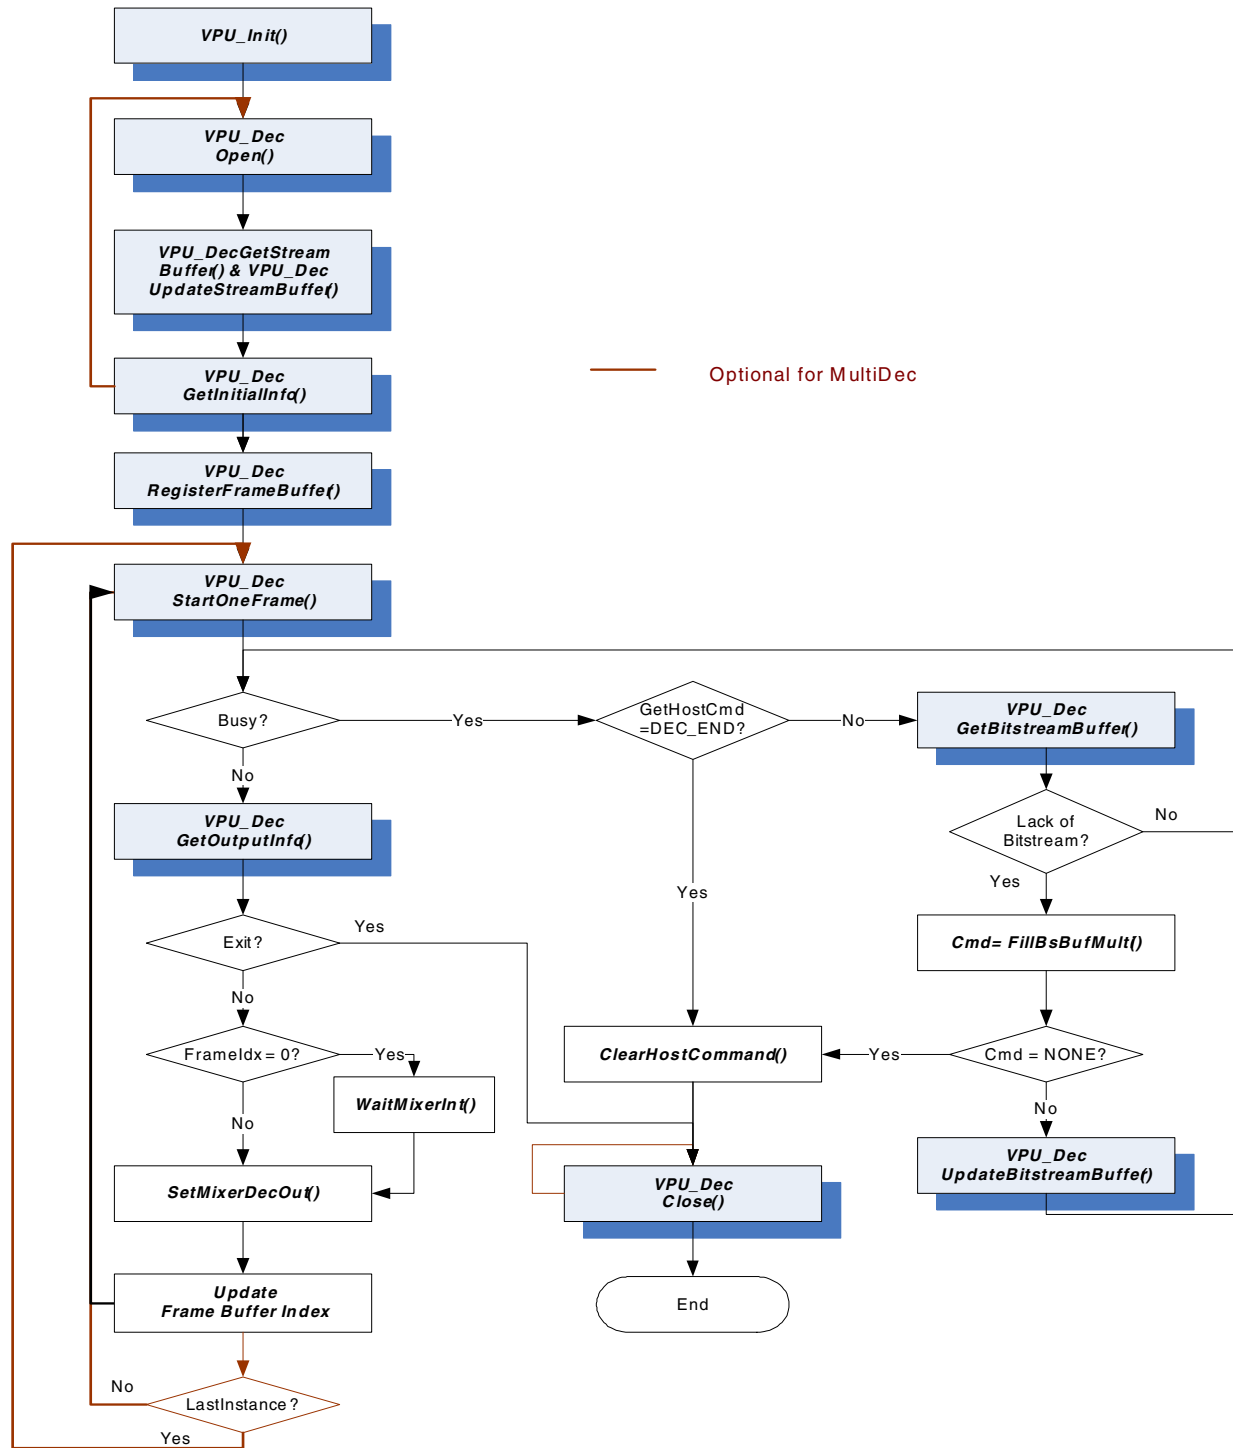

Figure 4. Decoder Operation Flow

### 3.3.1.3 MJPEG Decoding Operation Flow

The operation flow is different for a MJPEG bitstream because MJPEG decoding supports larger resolution. To save the physical buffer, the host application does not need to call **vpu\_DecRegisterFrameBuffer** to register the frame buffers because MJPEG decoding does not use a reference buffer. Instead, MJPEG decoding uses the same method as rotator decoding for other codecs to decode an image. Before calling **vpu\_DecStartOneFrame()**, the host application sends a SET\_ROTATOR\_STRIDE command to set the stride, and then sends a SET\_ROTATOR\_OUTPUT command to set the physical addresses of YCbCr components of output frame to save the decoded image. If the host application calls the **vpu\_DecRegisterFrameBuffer**, the function does nothing and returns success. Another difference is that the MJPEG decoder does not need to call **vpu\_DecClrDispFlag** to clear the display flag of frame buffer because there is no frame buffer in the MJPEG decoder.

### 3.3.1.4 Encoder Operation Flow

To encode a bitstream, the application completes the following steps:

1. Open a encoder instance using **vpu\_EncOpen()**
2. Before starting a picture encoder operation, get crucial parameters for encoder operations such as required frame buffer size using **vpu\_EncGetInitialInfo()**
3. Using the returned frame buffer requirement, allocate size of frame buffers and convey this information to the VPU using **vpu\_EncRegisterFrameBuffer()**
4. Generate high-level header syntaxes using **vpu\_EncGiveCommand()**
5. Start picture encoder operation picture-by-picture using **vpu\_EncStartOneFrame()**
6. Wait the completion of picture encoder operation interrupt event
7. After encoding a frame is complete, check the results of encoder operation using **vpu\_EncGetOutputInfo()**
8. If there are more frames to encode, go to Step 4, otherwise go to the next step
9. Terminate the sequence operation by closing the instance using **vpu\_EncClose()**

The encoder operation flow is shown in [Figure 5](#).

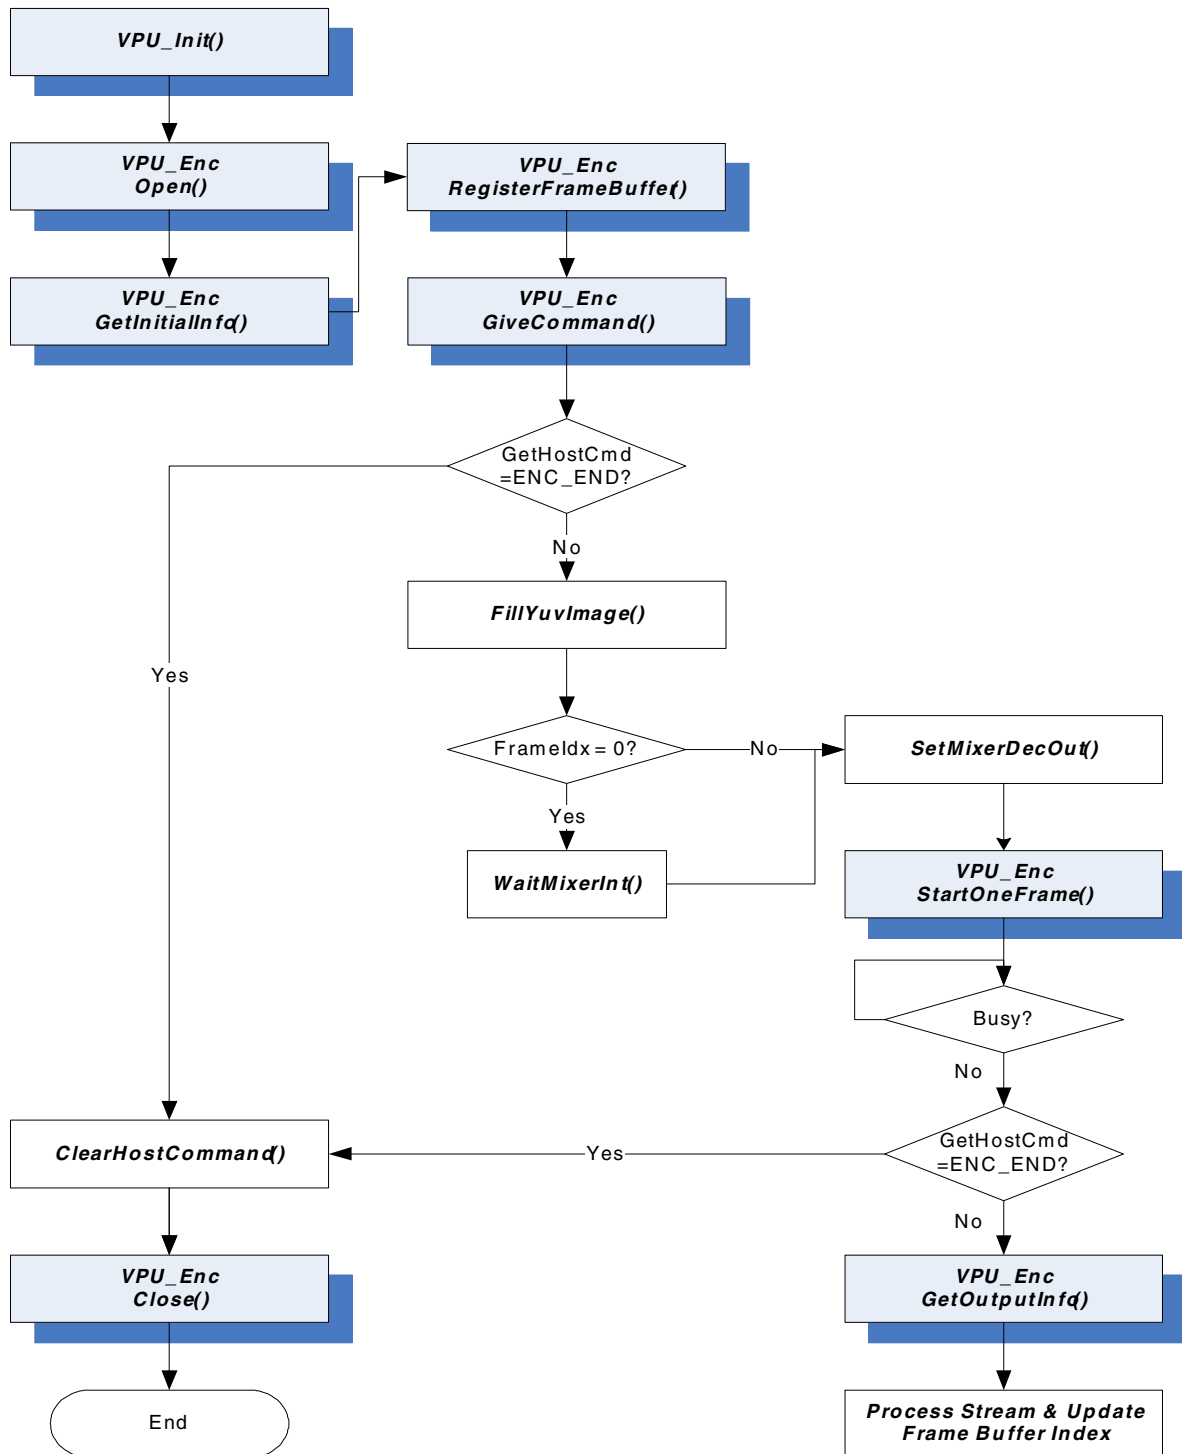

Figure 5. Encoder Operation Flow

### 3.3.2 Control API

The following sections describe the control API functions.

#### 3.3.2.1 vpu\_Init()

##### Prototype

```
RetCode vpu_Init(void);
```

##### Parameter

None

##### Return Value

RETCODE_SUCCESS	VPU initialized successfully
RETCODE_CALLED_BEFORE	Function call is invalid because multiple calls of the current API function for a given instance are not allowed. In this case, The VPU has been already initialized, and this function call is meaningless.
RETCODE_FAILURE	VPU initialization unsuccessful

##### Description

This function initializes the VPU hardware and proper data structures/resources. The application must call this function only once before using the VPU.

#### 3.3.2.2 vpu\_Deinit()

##### Prototype

```
RetCode vpu_Deinit(void);
```

##### Parameter

None

##### Return Value

RETCODE_NOT_INITIALIZED	VPU not initialized before calling this function. The application should initialize VPU by calling <b>vpu_Init()</b> before calling this function.
RETCODE_SUCCESS	VPU deinitialized successfully
RETCODE_FAILURE	VPU deinitialized unsuccessfully

##### Description

This function deinitializes the VPU hardware and releases the resources that are allocated in the **vpu\_Init()** function. The application must call this function before exiting.

### 3.3.2.3 vpu\_IsBusy()

#### Prototype

```
RetCode vpu_IsBusy(void);
```

#### Parameter

None

#### Return Value

RETCODE_NOT_INITIALIZED	VPU not initialized before calling this function. The application should initialize VPU by calling <b>vpu_Init()</b> before calling this function.
RETCODE_BUSY	VPU hardware is busy processing a frame
RETCODE_IDLE	VPU hardware is idle
RETCODE_FAILURE	Operation unsuccessful

#### Description

This function tells the application if decoder or encoder frame processing is completed or not at any time.

### 3.3.2.4 vpu\_GetVersionInfo()

#### Prototype

```
RetCode vpu_GetVersionInfo(Unit32 *versionInfo);
```

#### Parameter

versionInfo	[output] The 16 most significant bits are the product ID and the 16 least significant bits are the firmware version ID.
-------------	---

#### Return Value

RETCODE_SUCCESS	Version information acquired successfully
RETCODE_FAILURE	Current firmware does not contain any version information
RETCODE_NOT_INITIALIZED	VPU not initialized before calling this function. The application should initialize VPU by calling <b>vpu_Init()</b> before calling this function.

#### Description

This function provides the version information running on the system to the application.

### 3.3.2.5 vpu\_AllocPhysMem()

#### Prototype

```
RetCode vpu_AllocPhysMem(UINT32 cbSize, VPUMemAlloc *pmemalloc);
```

#### Parameter

cbSize	[input] Number of bytes to allocate
--------	-------------------------------------

**pmemalloc** [output] Pointer to a VPUMemAlloc that stores the physical/virtual address of the memory allocation

#### Return Value

RETCODE\_SUCCESS Allocation successful  
 RETCODE\_FAILURE Allocation failed

#### Description

This function allocates physically contiguous memory and the corresponding virtual memory in user space. When the application calls this function, the driver allocates physically contiguous memory and reserves a region of pages in the virtual address space for the host application.

### 3.3.2.6 vpu\_FreePhysMem()

#### Prototype

```
RetCode vpu_FreePhysMem(VPUMemAlloc* pmemalloc);
```

#### Parameter

**pmemalloc** [input] Pointer to a VPUMemAlloc that stores the allocated physical/virtual address of the memory

#### Return Value

RETCODE\_SUCCESS Deallocation successful  
 RETCODE\_FAILURE Deallocation failed

#### Description

This function frees the physical memory allocated by vpu\_AllocPhysMem back to the system.

### 3.3.2.7 vpu\_GetPhysAddrFromVirtAddr()

#### Prototype

```
RetCode vpu_GetPhysAddrFromVirtAddr(void* lpvAddress, Uint32 cbSize, PhysicalAddress* lppAddress);
```

#### Parameter

**lpvAddress** [input] Pointer to a virtual memory to be translated  
**cbSize** [input] Number of bytes to be translated  
**lppAddress** [output] Pointer to physical memory corresponding to the lpvAddress

#### Return Value

RETCODE\_SUCCESS Address retrieved successfully  
 RETCODE\_FAILURE Address retrieval failed  
 RETCODE\_NOT\_INITIALIZED VPU not initialized before calling this function. The application should initialize VPU by calling **vpu\_Init()** before calling this function.

## Description

This function retrieves the physical address of the given virtual address. To improve the performance, the VPU may use the display memory directly as frame buffers. The virtual memory address of the display memory can only be retrieved by the DirectDraw interface, but the VPU must access physically contiguous memory as the frame buffers. This function allows the host application to get the physical memory address from the virtual memory address.

### 3.3.2.8 vpu\_Reset()

#### Prototype

```
RetCode vpu_Reset(CoDecHandle handle, int index);
```

#### Parameter

handle [input] Encoder/decoder handle obtained from **vpu\_EncOpen()**/**vpu\_DecOpen()**  
 index [input] Index of instance to reset

#### Return Value

RETCODE\_SUCCESS: VPU reset successfully  
 RETCODE\_FAILURE VPU reset failed  
 RETCODE\_INVALID\_PARAM Given argument parameter, index, is invalid, which means the index is larger than the maximum index value, 4  
 RETCODE\_INVALID\_HANDLE Given handle for current API function call, handle, is invalid

#### Description

This function resets the instance specified by the handle or index. The host application uses this function in two ways:

- Call with handle parameter. If handle is given, the index parameter is ignored. After call, all context of handle instance is lost and cannot be used again. Therefore, the host must call **vpu\_DecClose()** to release the resources. In order to use this instance again, host must re-open the instance.
- Call with index parameter. This method is for the special case in which the application exists without instance closed, the resources need to be released and the host knows the instance index.

In normal operation, it is encouraged to reset the VPU with a specified handle. Resetting the VPU with an index parameter is not recommended.

## 3.3.3 Encoder API

The following sections describe the encoder API functions.

### 3.3.3.1 vpu\_EncOpen()

#### Prototype

```
RetCode vpu_EncOpen (EncHandle * pHandle, EncOpenParam * pOpenParam);
```

**Parameter**

pHandle	[output] Pointer to EncHandle type variable which specifies instance for an application. If no instance is available, a null handle is returned.
pOpenParam	[input] Pointer to a EncOpenParam type structure which describes the parameters for the new encoder instance.

**Return Value**

RETCODE_SUCCESS	New encoder instance opened successfully
RETCODE_FAILURE	New encoder instance not opened successfully. If there is no free instance available, this value is returned in the function call.
RETCODE_INVALID_PARAM	Given argument parameter, pOpenParam, is invalid—it has a null pointer or contains improper values for some member variables.
RETCODE_NOT_INITIALIZED	VPU not initialized before calling this function. The application must initialize VPU by calling <b>vpu_Init()</b> before calling this function.
RETCODE_FAILURE_TIMEOUT	This value might mean that the hardware is busy with another operation and unavailable for the current API call.

**Description**

To start a new encoder operation, the application must open a new instance for this encoder operation. By calling this function, the application gets a handle specifying a new encoder instance. Because the i.MX51 VPU supports multiple instances of codec operations, the application needs this kind of handle for the all running codec instances. Once the application received a handle, the application uses this handle to represent the target instances for all subsequent encoder-related operations.

**3.3.3.2 vpu\_EncClose()****Prototype**

```
RetCode vpu_EncClose(EncHandle handle);
```

**Parameter**

handle	[input] Encoder handle obtained from <b>vpu_EncOpen()</b>
--------	---

**Return Value**

RETCODE_SUCCESS	Encoder instance closed successfully
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be returned if handle has not been obtained by <b>vpu_EncOpen()</b> , for example a decoder handle, or if handle is of an instance which has been closed.
RETCODE_FAILURE_TIMEOUT	The value might mean that the hardware is busy with an other operation and unavailable for the current API call.

## Description

This function is called by the application to close an instance when the application completes the encoding operations and wants to release this instance for other processing. After completion of this function call, the instance referred to by handle is free. Once the application closes an instance, the application cannot call any further encoder-specific function with this handle before re-opening a new instance with the same handle.

### 3.3.3.3 vpu\_EncGetBitstreamBuffer()

#### Prototype

```
RetCode vpu_EncGetBitstreamBuffer(EncHandle handle, PhysicalAddress * pRdptr,
PhysicalAddress * pWrptr, Uint32 * size);
```

#### Parameter

handle	[input] Encoder handle obtained from <b>vpu_EncOpen()</b>
pRdptr	[output] Stream buffer read pointer for the current encoder instance
pWrptr	[output] Stream buffer write pointer for the current encoder instance
size	[output] Variable specifying the available space in the bitstream buffer for the current encoder instance

#### Return Value

RETCODE_SUCCESS	Required information for encoder stream buffer received successfully
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be returned if handle has not been obtained by <b>vpu_EncOpen()</b> , for example a decoder handle, or if handle is of an instance which has been closed.
RETCODE_INVALID_PARAM	Given argument parameters, pRdptr, pWrptr or size, are invalid—it has a null pointer or contains improper values for some member variables.

## Description

After encoding a frame, the application must get the bitstream from the encoder using the bitstream location and maximum size. The application gets this information by calling this function.

### 3.3.3.4 vpu\_EncUpdateBitstreamBuffer()

#### Prototype

```
RetCode vpu_EncUpdateBitstreamBuffer(EncHandle handle, Uint32 size);
```

#### Parameter

handle	[input] Encoder handle obtained from <b>vpu_EncOpen()</b>
size	[input] Variable specifying the amount of bits to get from the bitstream buffer for the current encoder instance

**Return Value**

RETCODE_SUCCESS	Putting new stream data completed successfully
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be returned if handle has not been obtained by <b>vpu_EncOpen()</b> , for example a decoder handle, or if handle is of an instance which has been closed.
RETCODE_INVALID_PARAM	Given argument parameter, size, is invalid—it is larger than the value obtained from <b>vpu_EncGetBitstreamBuffer()</b>

**Description**

The application must let encoder know how much bitstream has been transferred from the address obtained from **vpu\_EncGetBitstreamBuffer()**. By giving the size as an argument, the API automatically handles pointer wrap-around and updates the read pointer.

**3.3.3.5 vpu\_EncGetInitialInfo()****Prototype**

```
RetCode vpu_EncGetInitialInfo(EncHandle handle, EncInitialInfo * pInitialInfo);
```

**Parameter**

handle	[input] Encoder handle obtained from <b>vpu_EncOpen()</b>
pInitialInfo	[output] Pointer to a EncInitialInfo type structure which describes the parameters required before starting encoder operations

**Return Value**

RETCODE_SUCCESS	Receiving the initial parameters completed successfully
RETCODE_FAILURE	There is an error getting the configuration information for the encoder
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be returned if handle has not been obtained by <b>vpu_EncOpen()</b> , for example a decoder handle, or if handle is of an instance which has been closed.
RETCODE_INVALID_PARAM	The given argument parameter, pInitialInfo, is invalid—it has a null pointer or contains improper values for some member variables.
RETCODE_CALLED_BEFORE	Function call is invalid because multiple calls of the current API function for a given instance are not allowed. The encoder initial information has already been received, so this function call is meaningless and not allowed.
RETCODE_FAILURE_TIMEOUT	There is an time-out error in the function and the driver did not receive an interrupt after sending the initial command to the VPU
RETCODE_CALLED_BEFORE	Function has been called before

## Description

Before starting an encoder operation, the application must allocate the frame buffers according to the information obtained from this function. This function returns the required parameters for **vpu\_EncRegisterFrameBuffer()**, which is followed by this function call.

### 3.3.3.6 vpu\_EncRegisterFrameBuffer()

#### Prototype

```
RetCode vpu_EncRegisterFrameBuffer (EncHandle handle, FrameBuffer * pBuffer, int num, int stride);
```

#### Parameter

handle	[input] Encoder handle obtained from <b>vpu_EncOpen()</b>
pBuffer	[input] Pointer to a FrameBuffer type structure which describes the frame buffer pointer parameters for the current encoder instance
num	[input] Number of frame buffers
stride	[input] Stride value of the given frame buffers

The distance between a pixel in a row and the corresponding pixel in the next row is called stride. The value of stride must be a multiple of 8. The address of the first pixel in the second row does not necessarily coincide with the value next to the last pixel in the first row. In other words, stride can have values greater than the picture width in pixels. The application should not set a stride value smaller than the picture width. For the Y component, the application must allocate at least a space of size (frame height  $\times$  stride), and for Cb or Cr components, (frame height/2  $\times$  stride/2). For MJPEG encoding, the address of the frame buffer is not necessary. Only the stride value is necessary which is used as the source image stride.

#### Return Value

RETCODE_SUCCESS	Registering the frame buffers completed successfully
RETCODE_FAILURE	There is an error in registering the frame buffer for the encoder
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be returned if handle has not been obtained by <b>vpu_EncOpen()</b> , for example a decoder handle, or if handle is of an instance which has been closed.
RETCODE_WRONG_CALL_SEQUENCE	Current API function call is invalid considering the allowed sequences between API functions. In this case, the application may have called this function before successfully calling <b>vpu_EncGetInitialInfo()</b> . This function should be called after successfully calling <b>vpu_EncGetInitialInfo()</b> .
RETCODE_INVALID_FRAME_BUFFER	Argument pBuffer is invalid and is not initialized or is not valid.

**RETCODE\_INSUFFICIENT\_FRAME\_BUFFERS**

Given number of frame buffers, num, is not enough for the encoder operations of the given handle. num should be greater than or equal to the value of minFrameBufferCount obtained from **vpu\_EncGetInitialInfo()**.

**RETCODE\_INVALID\_STRIDE** Given argument stride is invalid—it is 0 or is not a multiple of 8

**RETCODE\_CALLED\_BEFORE** Function call is invalid because multiple calls of the current API function for a given instance are not allowed. The encoder initial information has already been received, so this function call is meaningless and not allowed.

**RETCODE\_FAILURE\_TIMEOUT**

There is an time-out error in the function and the driver did not receive an interrupt after sending the initial command to the VPU

**Description**

This function registers frame buffers requested by **vpu\_EncGetInitialInfo()**. The frame buffers pointed to by pBuffer are managed internally within the VPU. These include reference frames, reconstructed frames, and so on. The application must not change the contents of the array of frame buffers during the life time of the instance, and num must not be less than minFrameBufferCount obtained by **vpu\_EncGetInitialInfo()**.

**3.3.3.7 vpu\_EncStartOneFrame()****Prototype**

```
RetCode vpu_EncStartOneFrame (EncHandle handle, EncParam * pParam);
```

**Parameter**

handle	[input] Encoder handle obtained from <b>vpu_EncOpen()</b>
pParam	[input] Pointer to a EncParam type structure which describes picture encoding parameters for the current encoder instance

**Return Value**

<b>RETCODE_SUCCESS</b>	Encoding a new frame started successfully. This return value does not mean that encoding a frame completed successfully.
<b>RETCODE_FAILURE</b>	There is an error in starting one frame encoding operation
<b>RETCODE_INVALID_HANDLE</b>	Given handle for current API function call, handle, is invalid. This return code might be returned if handle has not been obtained by <b>vpu_EncOpen()</b> , for example a decoder handle, or if handle is of an instance which has been closed.

**RETCODE\_WRONG\_CALL\_SEQUENCE**

Current API function call is invalid considering the allowed sequences between API functions. In this case, the application may have called this function before successfully calling

**vpu\_EncRegisterFrameBuffer()**. This function should be called after successfully calling **vpu\_EncRegisterFrameBuffer()**.

**RETCODE\_INVALID\_PARAM** The given argument parameter, pParam, is invalid—it has a null pointer or contains improper values for some member variables.

**RETCODE\_INVALID\_FRAME\_BUFFER**  
sourceFrame in the input structure EncParam is invalid—  
sourceFrame is not valid even though picture-skip is disabled

### Description

This function starts encoding one frame. Returning from this function does not mean the completion of encoding one frame, but it just initiates encoding one frame. This function should be followed by **vpu\_EncGetOutputInfo()** with the same encoder handle. Before that, the application can not call another API function except for **vpu\_IsBusy()**, **vpu\_EncGetBitstreamBuffer()**, and **vpu\_EncUpdateBitstreamBuffer()**.

### 3.3.3.8 vpu\_EncGetOutputInfo()

#### Prototype

```
RetCode vpu_EncStartOneFrame(EncHandle handle, EncOutputInfo * pInfo);
```

#### Parameter

**handle** [input] Encoder handle obtained from **vpu\_EncOpen()**  
**pInfo** [output] Pointer to a EncOutputInfo type structure which describes picture encoding results for the current encoder instance

#### Return Value

**RETCODE\_SUCCESS** Output information of current frame encoding received successfully  
**RETCODE\_FAILURE** There is an error in getting the output information after one frame encoding command  
**RETCODE\_INVALID\_HANDLE** Given handle for current API function call, handle, is invalid. This return code might be returned if handle has not been obtained by **vpu\_EncOpen()**, for example a decoder handle, or if handle is of an instance which has been closed.  
**RETCODE\_WRONG\_CALL\_SEQUENCE** Current API function call is invalid considering the allowed sequences between API functions. In this case, the application may have called this function before successfully calling **vpu\_EncStartOneFrame()**. This function should be called after successfully calling **vpu\_EncStartOneFrame()**.  
**RETCODE\_INVALID\_PARAM** The given argument parameter, pInfo, is invalid—it has a null pointer or contains improper values for some member variables.

## Description

This function gets the information about the encoding output. The application can know about picture type, the address and size of the generated bitstream, the number of generated slices, the end addresses of the slices, and the macroblock bit position information. The host application calls this function after frame encoding is finished, and before starting the further processing. **vpu\_EncStartOneFrame()** and **vpu\_EncGetOutputInfo()** must be matched and must be called in the same thread.

### 3.3.3.9 vpu\_EncGiveCommand()

#### Prototype

```
RetCode vpu_EncGiveCommand (EncHandle handle, CodecCommand cmd, void * pParam);
```

#### Parameter

handle	[input] Encoder handle obtained from <b>vpu_EncOpen()</b>
cmd	[input] Variable specifying the command of CodecCommand type
pParam	[input/output] Pointer to a command-specific data structure which describes picture I/O parameters for the current encoder instance

#### Return Value

RETCODE_INVALID_COMMAND	Given argument, cmd, is invalid—it is undefined or not allowed in the current instance
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be returned if handle has not been obtained by <b>vpu_EncOpen()</b> , for example a decoder handle, or if handle is of an instance which has been closed.
RETCODE_FRAME_NOT_COMPLETE	Frame decoding or encoding operation is not complete, so the given API function call cannot be performed this time. A frame encoding or decoding operation should be completed by calling <b>vpu_EncGetOutputInfo()</b> or <b>vpu_DecGetOutputInfo()</b> . Even though the result of the current frame operation is not necessary, the application should call <b>vpu_EncGetOutputInfo()</b> or <b>vpu_DecGetOutputInfo()</b> to proceed this function call.

## Description

This function is provided to give applications a certain level of freedom for reconfiguring encoder operations after creating an encoder instance. The options which can be changed dynamically while encoding a video sequence as well as some command-specific return codes are shown in [Table 5](#).

**Table 5. Encoder Commands**

Command	Description						
ENABLE_ROTATION	This command enables rotation of the post-rotator. pParam is ignored. This command returns RETCODE_SUCCESS.						
DISABLE_ROTATION	This command disables rotation of the post-rotator. pParam is ignored. This command returns RETCODE_SUCCESS.						
ENABLE_MIRRORING	This command enables mirroring of the post-rotator. pParam is ignored. This command returns RETCODE_SUCCESS.						
DISABLE_MIRRORING	This command disables mirroring of the post-rotator. pParam is ignored. This command returns RETCODE_SUCCESS.						
SET_MIRROR_DIRECTION	<p>This command sets the mirror direction of the post-rotator. pParam is a pointer to MirrorDirection. *pParam should be one of the following:</p> <ul style="list-style-type: none"> <li>• MIRROR_NONE—No mirroring</li> <li>• MIRROR_VER—Vertical mirroring</li> <li>• MIRROR_HOR—Horizontal mirroring</li> <li>• MIRROR_HOR_VER—Both directions</li> </ul> <p>Return values are as follows:</p> <table> <tr> <td>RETCODE_SUCCESS</td><td>Given mirroring direction is valid</td></tr> <tr> <td>RETCODE_INVALID_PARAM</td><td>Given argument parameter, pParam, is invalid so given mirroring direction is invalid</td></tr> </table>	RETCODE_SUCCESS	Given mirroring direction is valid	RETCODE_INVALID_PARAM	Given argument parameter, pParam, is invalid so given mirroring direction is invalid		
RETCODE_SUCCESS	Given mirroring direction is valid						
RETCODE_INVALID_PARAM	Given argument parameter, pParam, is invalid so given mirroring direction is invalid						
SET_ROTATION_ANGLE	<p>This command sets the counter-clockwise angle for post-rotation. pParam a pointer to an integer which represents rotation angle in degrees. Rotation angle should be 0, 90, 180, or 270. Return values are as follows:</p> <table> <tr> <td>RETCODE_SUCCESS</td><td>Given rotation angle is valid</td></tr> <tr> <td>RETCODE_INVALID_PARAM</td><td>Given argument parameter, pParam, is invalid so given rotation angle is invalid</td></tr> </table> <p><b>Note:</b> Rotation angle can not be changed after sequence initialization, because it might cause problems in handling frame buffers.</p>	RETCODE_SUCCESS	Given rotation angle is valid	RETCODE_INVALID_PARAM	Given argument parameter, pParam, is invalid so given rotation angle is invalid		
RETCODE_SUCCESS	Given rotation angle is valid						
RETCODE_INVALID_PARAM	Given argument parameter, pParam, is invalid so given rotation angle is invalid						
ENC_GET_SPS_RBSP	<p>pParam is a pointer to an EncParamSet type structure. The first variable, paraSet, is a physical address where the generated stream is located, and size is the size of the stream in bytes. Return values are as follows:</p> <table> <tr> <td>RETCODE_SUCCESS</td><td>SPS successfully generated and available at the received buffer pointer</td></tr> <tr> <td>RETCODE_INVALID_COMMAND</td><td>Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an AVC (H.264) encoder instance.</td></tr> <tr> <td>RETCODE_INVALID_PARAM</td><td>Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables.</td></tr> </table>	RETCODE_SUCCESS	SPS successfully generated and available at the received buffer pointer	RETCODE_INVALID_COMMAND	Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an AVC (H.264) encoder instance.	RETCODE_INVALID_PARAM	Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables.
RETCODE_SUCCESS	SPS successfully generated and available at the received buffer pointer						
RETCODE_INVALID_COMMAND	Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an AVC (H.264) encoder instance.						
RETCODE_INVALID_PARAM	Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables.						

**Table 5. Encoder Commands (continued)**

Command	Description
ENC_GET_PPS_RBSP	<p>pParam is a pointer to an EncParamSet type structure. Return values are as follows:</p> <p>RETCODE_SUCCESS PPS successfully generated and available at the received buffer pointer</p> <p>RETCODE_INVALID_COMMAND Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an AVC (H.264) encoder instance.</p> <p>RETCODE_INVALID_PARAM Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables.</p>
ENC_PUT_MP4_HEADER	<p>pParam is a pointer to an EncHeaderParam structure, where buf is a physical address pointing to the generated stream location, and size is the size of the generated stream in bytes. headerType is a type of header that the application wants to generate and has values such as VOL_HEADER, VOS_HEADER, or VO_HEADER. Return values are as follows:</p> <p>RETCODE_SUCCESS Requested header syntax successfully inserted</p> <p>RETCODE_INVALID_COMMAND Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an MPEG-4 encoder instance.</p> <p>RETCODE_INVALID_PARAM Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables.</p>
ENC_PUT_AVC_HEADER	<p>pParam is a pointer to an EncHeaderParam structure, where buf is a physical address pointing the generated stream location and size is the size of generated stream in bytes. headerType is a type of header that the application wants to generate and has values such as SPS_RBSP or PPS_RBSP. Return values are as follows:</p> <p>RETCODE_SUCCESS Requested header syntax successfully inserted</p> <p>RETCODE_INVALID_COMMAND Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an AVC (H.264) encoder instance.</p> <p>RETCODE_INVALID_PARAM Given argument, pParam or headerType, is invalid—it has a null pointer or contains improper values for some member variables</p>
ENC_GET_VOS_HEADER	<p>Tells the encoder to generate a video object sequence (VOS) header stream based on the information provided when opening the instance for external usage (for example, out-of-band transmission). The generated stream is in RBSP format and big endian. Return values are as follows:</p> <p>RETCODE_SUCCESS VOS header information encoded successfully</p> <p>RETCODE_INVALID_COMMAND Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an MPEG-4 encoder instance.</p> <p>RETCODE_INVALID_PARAM Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables.</p> <p>RETCODE_FAILURE Command failed to executed due to unexpected errors</p>
ENC_GET_VO_HEADER	<p>Tells the encoder to generate a visual object (VO) header stream based on the information provided when opening the instance for external usage (for example, out-of-band transmission). The generated stream is in RBSP format and big endian. Return values are as follows:</p> <p>RETCODE_SUCCESS VO header information encoded successfully</p> <p>RETCODE_INVALID_COMMAND Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an MPEG-4 encoder instance.</p> <p>RETCODE_INVALID_PARAM Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables.</p> <p>RETCODE_FAILURE Command failed to executed due to unexpected errors</p>

**Table 5. Encoder Commands (continued)**

Command	Description
ENC_GET_VOL_HEADER	<p>Tells the encoder to generate a video object layer (VOL) header stream based on the information provided when opening the instance for external usage (for example, out-of-band transmission). The generated stream is in RBSP format and big endian. Return values are as follows:</p> <p>RETCODE_SUCCESS                      VOL header information encoded successfully</p> <p>RETCODE_INVALID_COMMAND            Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an MPEG-4 encoder instance.</p> <p>RETCODE_INVALID_PARAM              Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables.</p> <p>RETCODE_FAILURE                      Command failed to executed due to unexpected errors</p>
ENC_SET_INTRA_MB_REFRESH_NUMBER	<p>pParam is a pointer to an integer which represents the intra refresh number. The intra refresh number should be between 0 and the macroblock number of the encoded picture. Return values are as follows:</p> <p>RETCODE_SUCCESS                      Requested header syntax successfully inserted</p>
ENC_ENABLE_HEC	<p>pParam is ignored. Return values are as follows:</p> <p>RETCODE_SUCCESS                      Requested header syntax successfully inserted</p> <p>RETCODE_INVALID_COMMAND            Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an MPEG-4 encoder instance.</p>
ENC_DISABLE_HEC	<p>pParam is ignored. Return values are as follows:</p> <p>RETCODE_SUCCESS                      Requested header syntax successfully inserted</p> <p>RETCODE_INVALID_COMMAND            Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an MPEG-4 encoder instance.</p>
ENC_SET_SLICE_INFO	<p>pParam is a pointer to an EncSliceMode structure, where sliceMode enables a multi slice structure, sliceSizeMode represents the mode of calculating one slicesize, and sliceSize is the size of one slice. Return values are as follows:</p> <p>RETCODE_SUCCESS                      Requested header syntax successfully inserted</p> <p>RETCODE_INVALID_PARAM              Given argument parameter, pParam (EncSliceMode), is invalid—it has a null pointer or contains improper values for some member variables</p>
ENC_SET_GOP_NUMBER	<p>pParam is a pointer to an integer which represents the GOP number. Return values are as follows:</p> <p>RETCODE_SUCCESS                      Requested header syntax successfully inserted</p> <p>RETCODE_INVALID_PARAM              pParam is invalid—the given values for gopsize is an improper value</p>
ENC_SET_INTRA_QP	<p>pParam is a pointer to an integer which represents constant I frame QP. Constant I frame QP should be between 1 and 31 for MPEG-4, and between 0 and 51 for AVC (H.264). Return values are as follows:</p> <p>RETCODE_SUCCESS                      Requested header syntax successfully inserted</p> <p>RETCODE_INVALID_COMMAND            Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an encoder instance.</p> <p>RETCODE_INVALID_PARAM              Given argument parameter, pParam(QP value), is invalid—it has a null pointer or the given value for constance I frame QP is an improper value</p>

Table 5. Encoder Commands (continued)

Command	Description
ENC_SET_BITRATE	<p>pParam is a pointer to an integer which represents the bitrate. The bitrate should be between 0 and 32767. Return values are as follows:</p> <p>RETCODE_SUCCESS Requested header syntax successfully inserted</p> <p>RETCODE_INVALID_COMMAND Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an encoder instance.</p> <p>RETCODE_INVALID_PARAM The given argument parameter, pParam (Bitrate value), is invalid—it has a null pointer or the given value for bitrate is an improper value</p>
ENC_SET_FRAME_RATE	<p>pParam is a pointer to an integer which represents the frame rate value. The frame rate should be greater than 0. Return values are as follows:</p> <p>RETCODE_SUCCESS Requested header syntax inserted successfully</p> <p>RETCODE_INVALID_COMMAND Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, the current instance might not be an encoder instance.</p> <p>RETCODE_INVALID_PARAM Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables</p>
ENC_SET_REPORT_MBINFO	<p>pParam is a pointer to a type of ReportInfo. This command enables/disables the MB information report. If the host application enables the MB information report, the buffer used to save the MB information and its size must be set with the correct values that returns in <b>vpu_EncGetInitialInfo()</b>. The reported MB information is saved into the buffer set by this command. If the MB information report option is enabled, Slice Boundary and Qp are reported using 1byte as follows:</p> <p>Bit 7: Reserved</p> <p>Bit 6: Slice Boundary. Whenever new slice header is decoded, this bit field is toggled</p> <p>Bits 5:0: Macroblock Qp value</p> <p>Return values are as follows:</p> <p>RETCODE_SUCCESS Requested settings set successfully</p> <p>RETCODE_INVALID_PARAM Given parameters, buffer pointer or buffer size, is invalid—invalid parameter pointer or the buffer size is smaller than the required size.</p> <p>RETCODE_REPORT_BUF_NOT_SET Pointer to the MB information buffer is invalid</p>

**Table 5. Encoder Commands (continued)**

Command	Description
ENC_SET_REPORT_MVINFO	<p>pParam is a pointer to a type of ReportInfo. This command enables/disables the MV information report. If the host application enables the MV information report, the buffer used to save the MV information and its size must be set with the correct values that returns in <b>vpu_EncGetInitialInfo()</b>. The reported MV information is saved into the buffer set by this command. If the MV information option is enabled, Motion Vector information is reported using 4 bytes as follows:</p> <p>Bit 31: Intra Flag (1: intra, 0 inter)  Bits 30:16: X value of motion vector  Bits 16:0: Y value of motion vector</p> <p>Return values are as follows:</p> <p>RETCODE_SUCCESS Requested settings set successfully  RETCODE_INVALID_PARAM Given parameters, buffer pointer and buffer size, are invalid—invalid parameter pointer or the buffer size is smaller than the required size.  RETCODE_REPORT_BUF_NOT_SET  Pointer to the MV information buffer is invalid</p>
ENC_SET_REPORT_SLICEINFO	<p>pParam is a pointer to a type of ReportInfo. This command enables/disables the SliceInfo information report. If the host application enables the Slice information report, the buffer used to save the SliceInfo information and its size must be set with the correct values that returns in <b>vpu_EncGetInitialInfo()</b>. The reported SliceInfo information is saved into the buffer set by this command. If the SliceInfo information option is enabled, Slice information is reported using 8 bytes as follows:</p> <p>Bits 63:48: Reserved.  Bits 47:32: Last macroblock index of a slice (zero based-index)  Bits 31:0: Total number of bits used for encoding a slice</p> <p>Return values are as follows:</p> <p>RETCODE_SUCCESS Requested settings set successfully  RETCODE_INVALID_PARAM This means the given parameters, buffer pointer and buffer size, are invalid—invalid parameter pointer or the buffer size is smaller than the required size.  RETCODE_REPORT_BUF_NOT_SET  Pointer to the SliceInfo buffer is invalid</p>

### 3.3.4 Decoder API

The following sections describe the decoder API functions.

#### 3.3.4.1 vpu\_DecOpen()

##### Prototype

```
RetCode vpu_DecOpen(DecHandle * pHandle, DecOpenParam * pOpenParam);
```

##### Parameter

pHandle	[output] Pointer to a DecHandle type variable which specifies each instance for an application
pOpenParam	[input] Pointer to a DecOpenParam type structure which describes the required parameters for creating a new decoder instance

**Return Value**

RETCODE_SUCCESS	New decoder instance created successfully
RETCODE_FAILURE	New decoder instance not opened successfully. If there is no free instance available, this value is returned in the function call.
RETCODE_INVALID_PARAM	Given argument parameter, pOpenParam, is invalid—it has a null pointer or contains improper values for some member variables.
RETCODE_NOT_INITIALIZED	VPU not initialized before calling this function. The application must initialize VPU by calling <b>vpu_Init()</b> before calling this function.
RETCODE_FAILURE_TIMEOUT	VPU is busy with another task or there is something wrong with the VPU. In normal operation, the API call should not return a RETCODE_FAILURE_TIMEOUT value. If the application receives this value, the VPU internal function may be corrupted.

**Description**

To decode, the application must open the decoder. By calling this function, the application receives a handle by which the application can refer to a decoder instance. Because the VPU is a multiple instance codec, the application requires this kind of handle. Once the application receives a handle, the application must pass the handle to all subsequent decoder-related functions.

**3.3.4.2 vpu\_DecClose()****Prototype**

```
RetCode vpu_DecClose(DecHandle handle);
```

**Parameter**

handle [input] Decoder handle obtained from **vpu\_DecOpen()**

**Return Value**

RETCODE_SUCCESS	Current decoder instance closed successfully
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be caused if handle has not been obtained by <b>vpu_DecOpen()</b> or if handle is of an instance which has been closed.
RETCODE_FAILURE_TIMEOUT	VPU is busy with another task or there is something wrong with the VPU. In normal operation, the API call should not return a RETCODE_FAILURE_TIMEOUT value. If the application receives this value, the VPU internal function may be corrupted.

**Description**

When the application is finished decoding a sequence and wants to release this instance for other processing, the application should close this instance. After completion of this function call, the instance referred to by handle is free. Once the application closes an instance, the application cannot call any further decoder-specific function with this handle before re-opening a new decoder instance with the same handle.

### 3.3.4.3 vpu\_DecGetInitialInfo()

#### Prototype

```
RetCode vpu_DecGetInitialInfo(DecHandle handle, DecInitialInfo * pInfo);
```

#### Parameter

handle	[input] Decoder handle obtained from <b>vpu_DecOpen()</b>
pInfo	[output] Pointer to a DecInitialInfo data structure

#### Return Value

RETCODE_SUCCESS	Required information of the stream data to be decoded received successfully
RETCODE_FAILURE:	There is an error in getting the configuration information for the decoder
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be caused if handle has not been obtained by <b>vpu_DecOpen()</b> or if handle is of an instance which has been closed.
RETCODE_INVALID_PARAM	Given argument parameter, pInfo, is invalid—it has a null pointer or contains improper values for some member variables.
RETCODE_FAILURE_TIMEOUT	VPU is busy with another task or there is something wrong with the VPU. In normal operation, the API call should not return a RETCODE_FAILURE_TIMEOUT value. If the application receives this value, the VPU internal function may be corrupted.
RETCODE_WRONG_CALL_SEQUENCE	Current API function call is invalid considering the allowed sequence between API functions. In this case, the application might call this function before successfully putting the bitstream into the buffer data by calling <b>vpu_DecUpdateBitstreamBuffer()</b> . In order to perform this functions call, the bitstream data including the sequence level header should be transferred into the bitstream buffer before calling <b>vpu_DecGetInitialInfo()</b> .
RETCODE_CALLED_BEFORE	Function call is invalid because multiple calls of the current API function for a given instance are not allowed. The decoder initial information has been already received, so this function call is meaningless and not allowed.

#### Description

The application must pass the address of a DecInitialInfo structure, where the decoder stores the information such as picture size, number of necessary frame buffers, and so on. For details, see the definition of the DecInitialInfo data structure in [Section 3.2.2.19, “DecInitialInfo.”](#) This function should be called after creating a decoder instance and before starting frame decoding. The application must provide sufficient amount of bitstream to the decoder by calling **vpu\_DecUpdateBitstreamBuffer()** so bitstream buffer does not empty before this function returns.

In file-play mode with MPEG-4 or H.264, **vpu\_DecGetInitialInfo()** operates only with sequence level header syntaxes which might be much smaller than the 256 byte minimum transfer unit. If the application cannot ensure to feed enough data for the stream, the application can use the forced escape option using **vpu\_DecSetEscSeqInit()**.

### 3.3.4.4 vpu\_DecSetEscSeqInit()

#### Prototype

```
RetCode vpu_DecSetEscSeqInit(DecHandle handle, int escape);
```

#### Parameter

handle [input] Decoder handle obtained from **vpu\_DecOpen()**  
 escape [input] Flag to enable or disable forced escape from SEQ\_INIT

#### Return Value

RETCODE\_SUCCESS Force escape flag successfully provided to the BIT processor  
 RETCODE\_INVALID\_HANDLE Given handle for current API function call, handle, is invalid. This return code might be caused if handle has not been obtained by **vpu\_DecOpen()** or if handle is of an instance which has been closed.  
 RETCODE\_FAILURE\_TIMEOUT VPU is busy with another task or there is something wrong with the VPU. In normal operation, the API call should not return a RETCODE\_FAILURE\_TIMEOUT value. If the application receives this value, the VPU internal function may be corrupted.

#### Description

This is a special function to provide a way of escaping the VPU hanging during DEQ\_SEQ\_INIT. When this flag is set to 1 and the stream buffer becomes empty, the VPU automatically terminates the DEC\_SEQ\_INIT operation. If the target application ensures that a high layer header syntax is periodically sent through the channel, the application does not need this option. However, if the target application cannot ensure that a high layer header syntax is periodically sent through the channel (such as file-play mode), this function is useful to avoid the VPU hanging because of crucial errors in the header syntax.

#### NOTE

This flag is applied to all decoder instances together; therefore, it is recommended to reset this flag to 0 after successfully finishing the sequence initialization.

### 3.3.4.5 vpu\_DecGetBitstreamBuffer()

#### Prototype

```
RetCode vpu_DecGetBitstreamBuffer(DecHandle handle, PhysicalAddress * pRdptr,  
PhysicalAddress * pWrptr, Uint32 * size);
```

#### Parameter

handle [input] Decoder handle obtained from **vpu\_DecOpen()**

pRdptr	[output] Stream buffer read pointer for the current decoder instance
pWrptr	[output] Stream buffer write pointer for the current decoder instance
size	[output] Variable specifying the available space in the bitstream buffer for the current decoder instance

**Return Value**

RETCODE_SUCCESS	Required information for the decoder stream buffer received successfully
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be caused if handle has not been obtained by <b>vpu_DecOpen()</b> or if handle is of an instance which has been closed.
RETCODE_INVALID_PARAM	Given argument parameter, pRdptr, pWrptr or size, is invalid—it has a null pointer or given values for some member variables have improper values.

**Description**

Before decoding a bitstream, the application must give the bitstream data to the decoder. First, the application must know where bitstream can be placed and the maximum size. The application received this information from this function. For the VPU, using the data from this function is more efficient than providing an arbitrary bitstream buffer to the decoder.

**NOTE**

The given size is the total sum of the free space in the ring buffer. So when the application downloads a bitstream of this given size, Wrptr can reach the end of the stream buffer. In this case, the application should wrap-around Wrptr to the beginning of the stream buffer and download the remaining bits. If not, the decoder operation can fail.

**3.3.4.6 vpu\_DecUpdateBitstreamBuffer()****Prototype**

```
RetCode vpu_DecUpdateBitstreamBuffer(DecHandle handle, Uint32 size);
```

**Parameter**

handle	[input] Decoder handle obtained from <b>vpu_DecOpen()</b>
size	[input] Variable specifying the amount of bits transferred into the bitstream buffer for the current decoder instance

**Return Value**

RETCODE_SUCCESS	Putting new stream data completed successfully
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be caused if handle has not been obtained by <b>vpu_DecOpen()</b> or if handle is of an instance which has been closed.

RETCODE_INVALID_PARAM	The given argument parameter, size, is invalid—it is larger than the value obtained from <b>vpu_DecGetBitstreamBuffer()</b> or larger than the available space in the bitstream buffer.
RETCODE_FAILURE_TIMEOUT	VPU is busy with another task or there is something wrong with the VPU. In normal operation, the API call should not return a RETCODE_FAILURE_TIMEOUT value. If the application receives this value, the VPU internal function may be corrupted.

### Description

The application must let decoder know how much bitstream has been transferred to the address obtained from **vpu\_DecGetBitstreamBuffer()**. By giving the size as argument, the API automatically handles pointer wrap-around and write pointer update.

### 3.3.4.7 vpu\_DecRegisterFrameBuffer()

#### Prototype

```
RetCode vpu_DecRegisterFrameBuffer(DecHandle handle, FrameBuffer * pBuffer, int num, int stride, DecBufInfo * pBufInfo);
```

#### Parameter

handle	[input] Decoder handle obtained from <b>vpu_DecOpen()</b>
pBuffer	[input] Pointer to a FrameBuffer type structure which describes the frame buffer pointer parameters for the current decoder instance
num	[input] Number of frame buffers
stride	[input] Stride value of the given frame buffers
pBufInfo	[input] Pointer to a DecBufInfo type structure which describes the additional work buffers. sliceSaveBuffer is only declared by this structure

#### Return Value

RETCODE_SUCCESS	Registering the frame buffer information completed successfully
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be caused if handle has not been obtained by <b>vpu_DecOpen()</b> or if handle is of an instance which has been closed.
RETCODE_FAILURE_TIMEOUT	VPU is busy with another task or there is something wrong with the VPU. In normal operation, the API call should not return a RETCODE_FAILURE_TIMEOUT value. If the application receives this value, the VPU internal function may be corrupted.
RETCODE_WRONG_CALL_SEQUENCE	Current API function call is invalid considering the allowed sequence between API functions. In this case, the application might have called this function before successfully calling <b>vpu_DecGetInitialInfo()</b> .

**RETCODE\_INVALID\_FRAME\_BUFFER**

pBuffer is invalid—it is not initialized or is not valid anymore

**RETCODE\_INSUFFICIENT\_FRAME\_BUFFERS**

Given number of frame buffers, num, is not enough for the decoder operations of the given handle. num should be greater than or equal to the value requested by **vpu\_DecGetInitialInfo()**.

**RETCODE\_INVALID\_STRIDE**

The given argument stride is invalid—it is smaller than the decoded picture width, or is not a multiple of 8.

**RETCODE\_CALLED\_BEFORE**

Function call is invalid because multiple calls of the current API function for a given instance are not allowed. The decoder initial information has been already received, so this function call is meaningless and not allowed.

**Description**

This function is used for registering frame buffers with the information from **vpu\_DecGetInitialInfo()**. The frame buffers pointed to by pBuffer are managed internally within the VPU. These include reference frames, reconstructed frame, and so on. The application must not change the contents of the array of frame buffers during the life time of the instance, and num must not be less than minFrameBufferCount obtained from **vpu\_DecGetInitialInfo()**. In MJPG decoding, the host application can skip this function call because there is no reference frame concept.

**3.3.4.8 vpu\_DecStartOneFrame()****Prototype**

```
RetCode vpu_DecStartOneFrame(DecHandle handle, DecParam *pParam);
```

**Parameter**

handle	[input] Decoder handle obtained from <b>vpu_DecOpen()</b>
pParam	[input] Pointer to a DecParam type structure that describes the picture decoding parameters for the current encoder instance

**Return Value**

RETCODE_SUCCESS	Decoding a new frame started successfully. This return value does not mean that decoding a frame completed successfully.
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be caused if handle has not been obtained by <b>vpu_DecOpen()</b> or if handle is of an instance which has been closed.
RETCODE_FAILURE_TIMEOUT	VPU is busy with another task or there is something wrong with the VPU. In normal operation, the API call should not return a RETCODE_FAILURE_TIMEOUT value. If the application receives this value, the VPU internal function may be corrupted.

**RETCODE\_WRONG\_CALL\_SEQUENCE**

Current API function call is invalid considering the allowed sequence between API functions. The application might have called this function before successfully calling **vpu\_DecRegisterFrameBuffer()**. This function should be called after successfully calling **vpu\_DecRegisterFrameBuffer ()**.

**Description**

This function starts decoding one frame. Returning from this function does not mean the completion of decoding one frame, but it just initiates decoding one frame. The host application should wait for the **VPU\_INT\_PIC\_RUN\_NAME**. If this event is signaled, then **vpu\_DecGetOutputInfo()** is called to get the decoded output information. Every call of this function should be matched with **vpu\_DecGetOutputInfo()** with the same handle. Before that, the application can not call other API functions except for **vpu\_IsBusy()**, **vpu\_DecGetBitstreamBuffer()**, and **vpu\_DecUpdateBitstreamBuffer()**.

When the application uses pre-scan mode, there is only a very small chance that the decoder may hang. For the VC-1 decoder, pre-scan mode is not supported. Do not use prescan mode for MPEG4 decoding or in file-play mode.

**3.3.4.9 vpu\_DecGetOutputInfo()****Prototype**

```
RetCode vpu_DecGetOutputInfo(DecHandle handle, DecOutputInfo * pInfo);
```

**Parameter**

handle	[input] Decoder handle obtained from <b>vpu_DecOpen()</b>
pInfo	[output] Pointer to a DecOutputInfo type structure which describes the picture decoding results for the current decoder instance

**Return Value**

RETCODE_SUCCESS	Receiving the output information of current frame completed successfully
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be caused if handle has not been obtained by <b>vpu_DecOpen()</b> or if handle is of an instance which has been closed. Also, this value is returned when <b>vpu_DecStartOneFrame()</b> is matched with <b>vpu_DecGetOutputInfo()</b> with different handles.

**RETCODE\_WRONG\_CALL\_SEQUENCE**

Current API function call is invalid considering the allowed sequence between API functions. **vpu\_DecStartOneFrame()** with the same handle might not have been called before calling this function

RETCODE_INVALID_PARAM	Given argument parameter, pInfo, is invalid—it has a null pointer or contains improper values for some member variables.
-----------------------	--

## Description

The application received the output information of the decoder by calling this function after the `VPU_INT_PIC_RUN_NAME` event is signaled. The output information includes the frame buffer information containing the reconstructed image. The host application calls this function after the frame decoding is finished and before starting further processing.

### NOTE

If pre-scan mode is enabled, the application should check `prescanResult`. If the value of `prescanResult = 0`, the other output information is meaningless. **`vpu_DecStartOneFrame()`** and **`vpu_DecGetOutputInfo()`** must be matched and called in the same thread.

### 3.3.4.10 `vpu_DecBitBufferFlush()`

#### Prototype

```
RetCode vpu_DecBitBufferFlush(DecHandle handle);
```

#### Parameter

`handle` [input] Decoder handle obtained from **`vpu_DecOpen()`**

#### Return Value

<code>RETCODE_SUCCESS</code>	Receiving the output information of the current frame completed successfully
<code>RETCODE_FAILURE_TIMEOUT</code>	VPU is busy with another task or there is something wrong with the VPU. In normal operation, the API call should not return a <code>RETCODE_FAILURE_TIMEOUT</code> value. If the application receives this value, the VPU internal function may be corrupted.
<code>RETCODE_INVALID_HANDLE</code>	Given handle for current API function call, <code>handle</code> , is invalid. This return code might be caused if <code>handle</code> has not been obtained by <b><code>vpu_DecOpen()</code></b> or if <code>handle</code> is of an instance which has been closed. Also, this value is returned when <b><code>vpu_DecStartOneFrame()</code></b> is matched with <b><code>vpu_DecGetOutputInfo()</code></b> with different handles.
<code>RETCODE_WRONG_CALL_SEQUENCE</code>	Current API function call is invalid considering the allowed sequence between API functions. <b><code>vpu_DecRegisterFrameBuffer()</code></b> with the same handle might not have been called before calling this function.

## Description

The application flushes the bitstream in the decoder bitstream buffer without decoding by calling this function. If the bitstream buffer is flushed, the read and write pointers of the bitstream buffer of each instance are set to the bitstream buffer start address.

### 3.3.4.11 vpu\_DecClrDispFlag()

#### Prototype

```
RetCode vpu_DecClrDispFlag(DecHandle handle, int index);
```

#### Parameter

handle	[input] Decoder handle obtained from <b>vpu_DecOpen()</b>
index	[input] Frame buffer index to be cleared

#### Return Value

RETCODE_SUCCESS	Receiving the output information of the current frame completed successfully
RETCODE_INVALID_HANDLE	Given handle for current API function call, handle, is invalid. This return code might be caused if handle has not been obtained by <b>vpu_DecOpen()</b> or if handle is of an instance which has been closed. Also, this value is returned when <b>vpu_DecStartOneFrame()</b> is matched with <b>vpu_DecGetOutputInfo()</b> with different handles.
RETCODE_WRONG_CALL_SEQUENCE	Current API function call is invalid considering the allowed sequence between API functions. <b>vpu_DecRegisterFrameBuffer()</b> with the same handle might not have been called before calling this function.
RETCODE_INVALID_PARAM	Given argument parameter, index, is invalid—it has improper values

#### Description

The application clears the display flag of each frame buffer by calling this function after creating a decoder instance. If the display flag of the frame buffer is cleared, the frame buffer can be used in the decoding process. Therefore, the application controls displaying a buffer by clearing the display flag which is set by the VPU at every display index output process.

### 3.3.4.12 vpu\_DecGiveCommand()

#### Prototype

```
RetCode vpu_DecGiveCommand(DecHandle handle, CodecCommand cmd, void * pParam);
```

#### Parameter

handle	[input] Decoder handle obtained from <b>vpu_DecOpen()</b>
cmd	[input] Variable specifying the given command of CodecCommand type
pParam	[input/output] Pointer to a command-specific data structure which describes picture I/O parameters for the current decoder instance

#### Return Value

RETCODE_INVALID_COMMAND	Given argument, cmd, is invalid—it is undefined or not allowed in the current instance
-------------------------	--

- RETCODE\_INVALID\_HANDLE** Given handle for current API function call, handle, is invalid. This return code might be caused if handle has not been obtained by **vpu\_DecOpen()** or if handle is of an instance which has been closed.
- RETCODE\_FAILURE\_TIMEOUT** VPU is busy with another task or there is something wrong with the VPU. In normal operation, the API call should not return a **RETCODE\_FAILURE\_TIMEOUT** value. If the application receives this value, the VPU internal function may be corrupted.

## Description

This function is provided to give applications a certain level of freedom for reconfiguring decoder operations after creating a decoder instance. The options which can be changed dynamically while decoding a video sequence as well as some command-specific return codes are shown in [Table 6](#).

**Table 6. Decoder Commands**

Command	Description				
ENABLE_ROTATION	Enables rotation of the post-rotator. pParam is ignored. Returns RETCODE_SUCCESS.				
DISABLE_ROTATION	Disables rotation of the post-rotator. pParam is ignored. Returns RETCODE_SUCCESS.				
ENABLE_MIRRORING	Enables mirroring of the post-rotator. pParam is ignored. Returns RETCODE_SUCCESS.				
DISABLE_MIRRORING	Disables mirroring of the post-rotator. pParam is ignored. Returns RETCODE_SUCCESS.				
SET_MIRROR_DIRECTION	<p>Sets the mirror direction of the post-rotator. pParam is a pointer to MirrorDirection. *pParam should be one of the following:</p> <ul style="list-style-type: none"> <li>MIRDIR_NONE—No mirroring</li> <li>MIRDIR_VER—Vertical mirroring</li> <li>MIRDIR_HOR—Horizontal mirroring</li> <li>MIRDIR_HOR_VER—Both directions</li> </ul> <p>Return values are as follows:</p> <table> <tr> <td>RETCODE_SUCCESS</td><td>Given mirroring direction is valid</td></tr> <tr> <td>RETCODE_INVALID_PARAM</td><td>Given argument parameter, pParam, is invalid so given mirroring direction is invalid</td></tr> </table>	RETCODE_SUCCESS	Given mirroring direction is valid	RETCODE_INVALID_PARAM	Given argument parameter, pParam, is invalid so given mirroring direction is invalid
RETCODE_SUCCESS	Given mirroring direction is valid				
RETCODE_INVALID_PARAM	Given argument parameter, pParam, is invalid so given mirroring direction is invalid				
SET_ROTATION_ANGLE	<p>Sets the counter-clockwise angle for post-rotation. pParam a pointer to an integer which represents rotation angle in degrees. The rotation angle should be 0, 90, 180, or 270. Return values are as follows:</p> <table> <tr> <td>RETCODE_SUCCESS</td><td>Given rotation angle is valid</td></tr> <tr> <td>RETCODE_INVALID_PARAM</td><td>Given argument parameter, pParam, is invalid so given rotation angle is invalid</td></tr> </table>	RETCODE_SUCCESS	Given rotation angle is valid	RETCODE_INVALID_PARAM	Given argument parameter, pParam, is invalid so given rotation angle is invalid
RETCODE_SUCCESS	Given rotation angle is valid				
RETCODE_INVALID_PARAM	Given argument parameter, pParam, is invalid so given rotation angle is invalid				
SET_ROTATOR_OUTPUT	<p>Sets the rotator output buffer address. pParam a pointer to a structure representing the physical addresses of the YCbCr components of the output frame. For storing the rotated output for a display, at least one more frame buffer should be allocated. When multiple display buffers are required, the application changes the buffer pointer of the rotated output at every frame by issuing this command. Return values are as follows:</p> <table> <tr> <td>RETCODE_SUCCESS</td><td>Given frame buffer pointer is valid</td></tr> <tr> <td>RETCODE_INVALID_PARAM</td><td>Given argument parameter, pParam, is invalid so given frame buffer pointer is invalid</td></tr> </table>	RETCODE_SUCCESS	Given frame buffer pointer is valid	RETCODE_INVALID_PARAM	Given argument parameter, pParam, is invalid so given frame buffer pointer is invalid
RETCODE_SUCCESS	Given frame buffer pointer is valid				
RETCODE_INVALID_PARAM	Given argument parameter, pParam, is invalid so given frame buffer pointer is invalid				

Table 6. Decoder Commands (continued)

Command	Description
SET_ROTATOR_STRIDE	<p>Sets the stride size of the frame buffer containing rotated output. pParam is the stride value of the rotated output. Return values are as follows:</p> <p>RETCODE_SUCCESS      Given stride value is valid</p> <p>RETCODE_INVALID_PARAM      Given argument parameter, pParam, is invalid so given stride value is invalid. The stride value must be greater than 0 and a multiple of 8.</p>
DEC_SET_SPS_RBSP	<p>Applies the SPS stream to the decoder received from a certain out-of-band reception scheme. The stream should be in RBSP format and big endian. pParam is a pointer to a DecParamSet structure. paraSet is an array of 32 bits which contains SPS RBSP, and size is the size of the stream in bytes. Return values are as follows:</p> <p>RETCODE_SUCCESS      Transferring a SPS RBSP to a decoder completed successfully</p> <p>RETCODE_INVALID_COMMAND      Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, the current instance might not be an AVC (H.264) decoder instance.</p> <p>RETCODE_INVALID_PARAM      Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables.</p>
DEC_SET_PPS_RBSP	<p>Applies the PPS stream to the decoder received from a certain out-of-band reception scheme. The stream should be in RBSP format and big endian. pParam is a pointer to a DecParamSet structure. paraSet is an array of 32 bits which contains PPS RBSP, and size is the size of the stream in bytes. Return values are as follows:</p> <p>RETCODE_SUCCESS      Transferring a PPS RBSP to decoder completed successfully</p> <p>RETCODE_INVALID_COMMAND      Given argument, cmd, is invalid—it is undefined or not allowed in the current instance. In this case, current instance might not be an AVC (H.264) decoder instance.</p> <p>RETCODE_INVALID_PARAM      Given argument, pParam, is invalid—it has a null pointer or contains improper values for some member variables.</p>
ENABLE_DERING	Enables the VPU internal dering operation. Returns RETCODE_SUCCESS.
DISABLE_DERING	Disables the VPU internal dering function. Returns RETCODE_SUCCESS.
DEC_SET_REPORT_BUFSTAT	<p>Enables/disables the frame buffers status report function. If the host application requires the frame buffer status information, it enables the function by setting this command with the allocated buffer from the user space with the correct size returned from <b>vpu_DecGetInitialInfo()</b>. The returned frame buffer status information is saved into this buffer after calling <b>vpu_DecGetOutputInfo()</b>. Each frame buffer can be used for display, for reference or not used. The decoder reports the frame buffer status of each frame using 4 bits as follows:</p> <p>Bit 3 set = Not used</p> <p>Bit 2 set = Display</p> <p>Bit 1 set = Reference</p> <p>Bit 0 set = Not used</p> <p>For example, if the value of the frame buffer status is 6, then the frame buffer is used for reference and display. If the value is 4, the frame buffer is used for display and is not used for reference.</p> <p>In H.264, bit field definition is as follows:</p> <p>Bit 3 set = Not used</p> <p>Bit 2 set = Display</p> <p>Bit 1 set = Out (Frame is in DPB buffer)</p> <p>Bit 0 set = Reference</p>

**Table 6. Decoder Commands (continued)**

Command	Description
DEC_SET_REPORT_MBINFO	<p>Enables/disables the MB information report function. If the host application requires the MB information, it enables the function by setting this command with the allocated buffer from the user space with the correct size returned from <b>vpu_DecGetInitialInfo()</b>. The returned MB parameter is saved into this buffer after calling <b>vpu_DecGetOutputInfo()</b>. If this option is enabled, error flag, Slice Boundary and Qp are reported using 8 bits as follows:</p> <p>Bit 7: Error Map. If error is detected in macroblock decoding, this bit field is set to 1</p> <p>Bit 6: Slice Boundary. Whenever new slice header is decoded, this bit field is toggled</p> <p>Bits 5:0: Macroblock Qp value</p> <p>Return values are as follows:</p> <p>RETCODE_SUCCESS                      Operation completed successfully</p> <p>RETCODE_INVALID_PARAM              Given argument parameter, param is invalid—it has a null pointer or addr in DecReportInfo is a null pointer when enable is 1.</p>
DEC_SET_REPORT_MVINFO	<p>This command enables/disables the Motion Vector (MV) information report function. If the host application requires the MV information, it enables the function by setting this command with the allocated buffer from the user space with the correct size returned from <b>vpu_DecGetInitialInfo()</b>. The returned MV information is saved into this buffer after calling <b>vpu_DecGetOutputInfo()</b>. If this option is enabled, the decoder reports a MV for P picture and two motion vectors for B picture. The MV information is reported using 4 bytes as follows:</p> <p>bit 31: Intra Flag (1: intra, 0 inter)</p> <p>[30:16] :X value of motion vector</p> <p>[16:0] : Y value of motion vector</p> <p>Return values are as follows:</p> <p>RETCODE_SUCCESS                      Operation completed successfully</p> <p>RETCODE_INVALID_PARAM              Given argument parameter, param. is invalid—it has a null pointer or addr in DecReportInfo is a null pointer when enable is 1.</p>

Table 6. Decoder Commands (continued)

Command	Description
DEC_SET_REPORT_USERDATA	<p>This command enables/disables the user data report function. If the host application requires the user data information, it enables the function by setting this command with the allocated buffer from the user space with the correct size returned from <code>vpu_DecGetInitialInfo()</code>. The returned user data information is saved into this buffer after calling <code>vpu_DecGetOutputInfo()</code>. The user data buffer full interrupt is issued if the user data buffer size is not large enough to save the user data during frame decoding. If the interrupt is issued, the decoder waits until the host clears the interrupt and restarts the user data by writing at the beginning of <code>userDataBufAddr</code> if the interrupt is cleared.</p> <p>If the user data report mode is 1, the decoder does not issue the interrupt and reports buffer size amount of user data. The size and address of the user data buffer, <code>userDataBufSize</code> and <code>userDataBufAddr</code>, should be multiple of 8. <code>userDataBufSize</code> does not include user data type and user data size as shown in Figure 6, Therefore, the host should allocate <math>8 \times 17 + \text{userDataBufSize}</math> bytes for the user data memory.</p> <p>To avoid complex implementation and considering that in most cases the user data size not large, the user data report mode is hard-coded as 1. If the user buffer size is too small to save all user data during frame decoding, the <code>userDataBufFull</code> in <code>ReportInfo</code> is set to indicate that the user data buffer overflowed. Figure 7 and Figure 8 show these two cases.</p> <p>According to codec standard, the user data type is set as follows:  For H.264 (For more details see the Annex D in the H.264 spec):  4: <code>user_data_registered_itu_t_t35</code>  5: <code>user_data_unregistered</code>  For VC1:  31: Sequence level user data  30: Entry-point level user data  29: Frame level user data  28: Field level user data  27: Slice level user data  For MP2:  0: Sequence user data  1: GOP user data  2: Picture user data  For MP4:  0: VOS user data  1: VIS user data  2: VOL user data  3: GOV user data  Return values are as follows:  <b>RETCODE_SUCCESS</b>                      Operation completed successfully  <b>RETCODE_INVALID_PARAM</b>              Given argument parameter, <code>param</code> is invalid—it has a null pointer or <code>addr</code> in <code>DecReportInfo</code> is a null pointer when <code>enable</code> is 1.</p>

Figure 6 shows the user data report structure where each of the 16 possible users are designated #0 User, #1 User, and so on. The data of the first user, #0 User, is the #0 User Data and the size of this data is #0 User Data Size. The User Data Size for users #0–15 is the size in bytes of the #0–15 User Data, excluding the zero padding (0 Padding) that is between each user data. The User Data Size is used to calculate the offset from the base, `userDataBufBase`, to the data for each user.

For example:

#1 User Data = `userDataBufBase` +  $8 \times 17$  + #0 User Data Size + 0 Padding

Where the size of the 0 Padding for each user is:

$$0 \text{ padding} = (8 - (\text{User Data Size} \% 8)) \% 8$$

For example, the 0 padding for User #0 =  $(8 - (\text{\#0 User Data Size} \% 8)) \% 8$

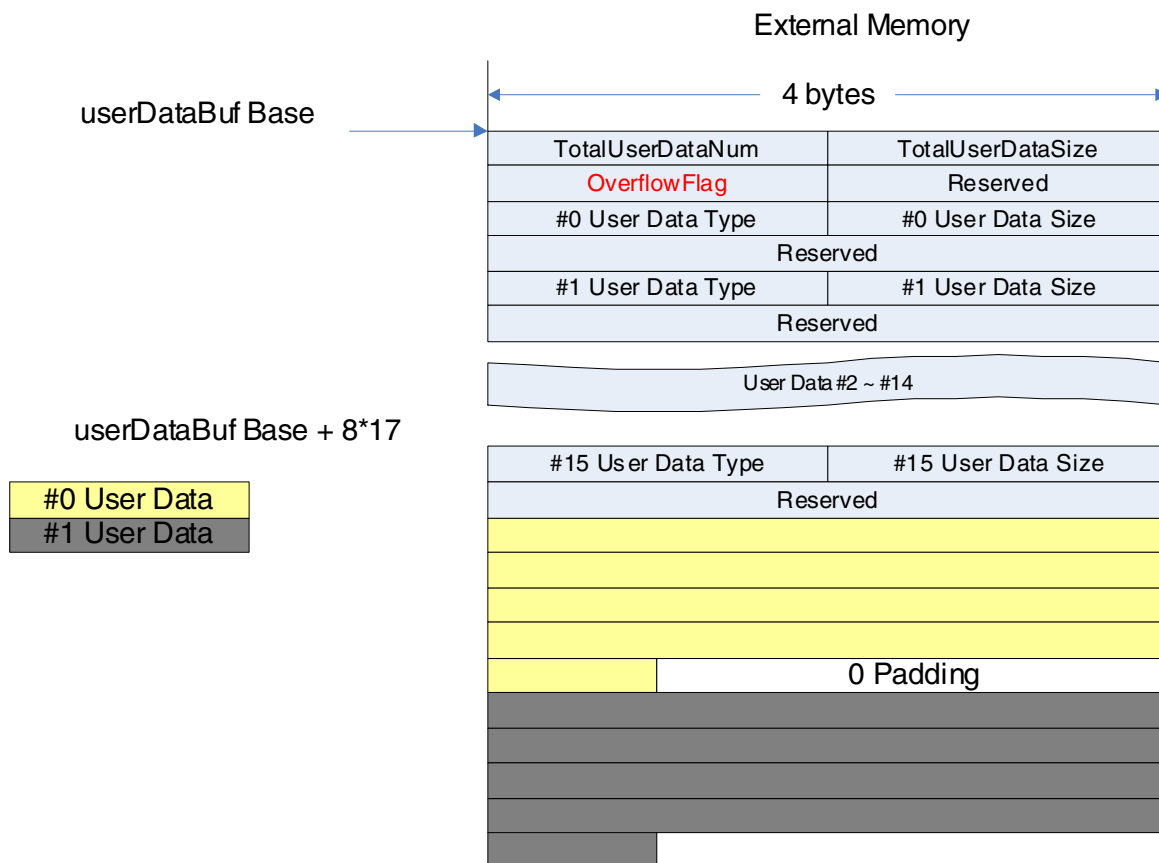

Figure 6. User Data Report Structure

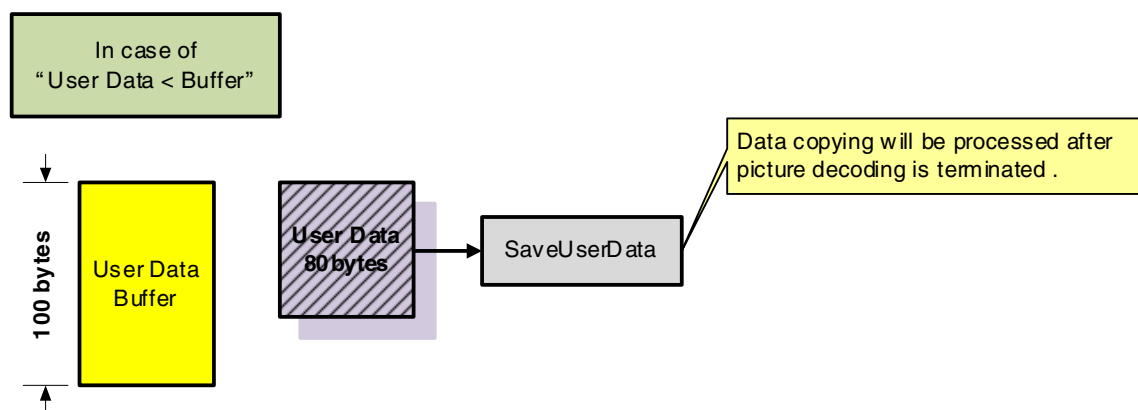

Figure 7. Normal Case: Amount of User Data is Less than Buffer Size

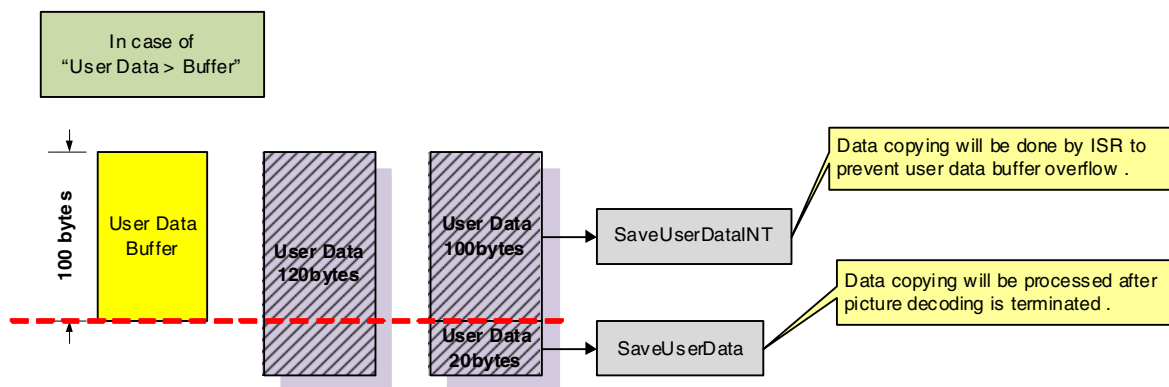

Figure 8. User Data Overflow Case

## 4 VPU Control

This section describes the VPU control scheme based on the API functions and includes some practical programming issues.

### 4.1 VPU Initialization

When the host processor enables the VPU for the first time, the following initialization process should be performed. These operations are completed by calling a single API function, **vpu\_Init()**.

- Disable the BIT processor by setting `BIT_CODE_RUN (BASE + 0x000) = 0`
- Write the BIT processor microcode to the SDRAM accessible by the VPU during run-time
- Download the first *N* Kbytes of microcode to the BIT processor code memory
- Set the BIT processor buffer pointers, working buffer, parameter buffer and code buffer
- Set the stream buffer control options and the frame buffer endian mode
- Enable interrupt and reset registers
- Enable the BIT processor by setting `BIT_CODE_RUN` register = 1
- Wait until **vpu\_IsBusy()** returns `RETCODE_IDLE`

Detailed information about each of these initialization steps and some programming tips are presented in the following sections.

#### 4.1.1 Version Check of BIT Processor Microcode

The application can check the version information of the BIT processor microcode during runtime. The version number of microcode is a 32-bit value. The 16 most significant bits are the internal product number, and the 16 least significant bits are the version number specified by the following rule:

- Bits 15:12 = Major revision
- Bits 11:8 = Minor revision
- Bits 7:0 = Revision patches

This version number can have a value from 0.0.0 to 15.15.255. A dedicated command, **vpu\_GetVersionInfo()**, is used for this version check and is supported after initialization.

### 4.1.2 BIT Processor Enable and Disable

The BIT processor has a dedicated register that activates or deactivates the BIT processor during run-time, **BIT\_CODE\_RUN** (BASE + 0x000). During initialization, the BIT processor program memory is updated and some configuration registers for controlling VPU operations are also set. During this process, the BIT processor should be disabled. After finishing the initialization process, the host processor enables the BIT processor. Then the BIT processor starts its own internal initialization process and is ready for operation.

### 4.1.3 BIT Processor Data Buffer Management

The BIT processor requires a certain amount of SDRAM space for its codec operations. This dedicated memory space includes memory space for the BIT processor microcode, internal work buffer, parameter buffers, and so on. The size of each sub-buffer as follows:

```
#define CODE_BUF_SIZE (128*1024)           // byte size of Code buffer
#define WORK_BUF_SIZE (256*1024)          // byte size of Work Buffer
#define PARA_BUF_SIZE (8*1024)            // byte size of Parameter Buffer
```

In the VPU API, the initialization function only receives the start address of this internal buffer as an argument. Therefore, the total sum of the VPU processing buffer space starting from the start address should be dedicated memory space for the VPU and no other process should access this memory space while the VPU is enabled. It is highly recommended for the host processor to reserve the specified size of the dedicated buffer for the BIT processor and call **vpu\_Init()** with the start address of the reserved memory. The start addresses of internal buffer partitions, code buffer, work buffer and parameter buffer, are calculated inside of the **vpu\_Init()** function and the calculated start addresses are set in the host interface.

In addition to the above sub-buffers, the VPU requires buffers for saving SPS/PPS and SLICE RBSP when decoding a H.264 stream. In general, 5 Kbytes is sufficient for the SPS/PPS save buffer and a quarter of the raw YUV image size is sufficient for the SLICE save buffer. If the VPU requires more buffer space to decode a H.264 stream, the VPU reports a buffer overflow.

### 4.1.4 BIT Processor Microcode Management

The BIT processor has its own program memory inside of the VPU, but the content of this program memory is dynamically updated according to the required codec standard. The advantage of this dynamic microcode reloading is the reduction of program memory size. This advantage is meaningful because the BIT processor generally requires many sets of microcode to support several codec standards in duplex mode. Generally speaking, it seldom happens that the codec standard is changed in the middle of a codec application. So dynamic reloading for changing the codec is not a burden in cycle consumption. In the worst case, the dynamic code reloading happens once per picture processing, but considering the amount of maximum reloaded code, it is not a large burden to the VPU cycle consumption.

Since the dynamic reloading is completed by the VPU itself, the host processor only needs to copy the given microcode to the reserved code buffer before initializing the VPU. Of course, the first loading of the microcode to the BIT processor program memory should be completed separately by the host processor.

### 4.1.5 Stream Buffer Management

The stream buffer is a shared buffer between the host processor and the VPU for exchanging stream data. There are two different streaming schemes for decoding: ring-buffer and line-buffer. The ring-buffer scheme is used for host applications to reserve a fixed size of memory space and use it during codec operations. On the other hand, the line buffer scheme is used for host application to allocate a stream buffer dynamically and use it frame-by-frame.

The host processor also can choose the endian option of the stream buffer and can enable or disable the buffer full/empty check option. All these options for stream buffer data management are stored in a dedicated host interface register, BIT\_BITSTREAM\_CTRL, and are referenced by the BIT processor during run-time.

For decoding, the VPU provides both streaming options. But sometimes multiple-instance decoding may require a different streaming option for each decoder instance. For example, while playing a local video file, the application might need to decode a digital video broadcast. In this case, the different types of streaming mode can be helpful for the application design and the different streaming option is applied to each decoder instance independently.

#### 4.1.5.1 Ring-Buffer Scheme (Packet Mode)

The ring-buffer scheme is preferred in packet-based video communication and streaming applications. In packet-based streaming based on a ring-buffer, the read and write pointers automatically wrap around at the boundaries. When the application downloads a new chunk of the bitstream, the application should check the available space in the bitstream buffer. Even though the available space can easily be calculated from the read pointer, write pointer and buffer size, the VPU API provides a dedicated function for providing the buffer read pointer, buffer write pointer and the available space in the stream buffer, **vpu\_DecGetBitStreamBuffer()**. Based on the returned value from this API function, the application downloads a new chunk of bitstream data whose size should be smaller than the available buffer space. The amount of bits transferred into the stream buffer should be notified to the VPU using **vpu\_DecUpdateBitStreamBuffer()**.

#### 4.1.5.2 Line-Buffer Scheme (File-Play Mode)

The line-buffer based streaming scheme is suitable for local file-play applications where a picture stream is completely separated by file container structures. For decoding, the line-buffer based streaming scheme is only allowed if the application always sends the stream data for only one frame. This means, when the line-buffering scheme, or file-play mode, is enabled, the VPU resets the read pointer to the start address of the bitstream buffer.

File-play mode is used when an application allocates the bitstream buffer dynamically as dynamic buffer allocation is only allowed when file-play mode is enabled. As well as this dynamic buffer allocation option, the byte offset of each dynamically allocated stream buffer can be used to avoid unnecessary

stream copies because of the 8-byte alignment restriction in the VPU. By providing a byte offset between zero and three, the host application can avoid the overhead of coping the stream to an 8-byte aligned input stream buffer.

The application does not need to use two dedicated APIs, **vpu\_DecGetBitStreamBuffer()** and **vpu\_DecUpdateBitStreamBuffer()**. The start address and the size of bitstream buffer is provided as an argument of **vpu\_DecStartOneFrame()** to the VPU frame-by-frame.

### 4.1.6 Interrupt Signaling Management

To achieve maximum efficiency in VPU control, the VPU IP provides interrupt signaling for completion of a requested operation as well as stream buffer empty/full. For some commands with a quick return, interrupt signaling is not helpful so interrupt signaling is not provided.

The VPU provides interrupt signaling for the following commands:

- **BIT\_RUN\_COMPLETE**—BIT processor initialization complete after setting **BIT\_CODE\_RUN**
- **DEC\_SEQ\_INIT**—Decoder sequence initialization complete
- **DEC\_SEQ\_END**—Decoder sequence termination complete
- **DEC\_PIC\_RUN**—Decoder picture processing complete
- **DEC\_SET\_FRAME\_BUF**—Decoder frame buffer registration complete
- **DEC\_PARA\_SET**—External header syntax transfer to decoder complete
- **DEC\_BUF\_FLUSH**—Flushing decoder stream buffer complete

**DEC\_SEQ\_INIT** and **DEC\_PIC\_RUN** can cause the VPU to stall when the input bitstream is not large enough. So enabling the bitstream buffer-empty interrupt with these two interrupts, avoids unnecessary cycle consumptions in the host application. Each interrupt is easily enabled or disabled by writing 0 or 1 to the corresponding bit field of interrupt enable register. When an interrupt is signaled, the application checks the source of the interrupt by checking the value of interrupt reason register. When interrupt signaling is not easily applicable, these interrupt can be replaced by a polling scheme by reading the BIT processor busy-flag.

#### NOTE

Only the **DEC\_PIC\_RUN** interrupt is used by applications. The other interrupts are used internally by the API or not supported.

## 4.2 Encoder Control

### 4.2.1 Creating an Encoder Instance

After initialization of the VPU, an application creates an encode instance and acquires a handle for specifying that encoder instance as the first step to run an encoder operation. This is accomplished using a single API function called **vpu\_EncOpen()**.

When creating a new encoder instance, the application specifies the internal features of the encoder instance through the EncOpenParam structure. This structure includes the following information about the new encoder instance:

- Bitstream buffer address and size—Physical address of the bitstream buffer start and its size
- Codec standard—Video codec standard such as H.263, MPEG-4, H.264 or MJPEG
- Picture size—Picture width and height
- Target frame rate and bitrate with Video Buffer Verifier (VBB) model parameters, initialDelay and vbbBufferSize—VBB mode parameters are optional even when rate control is enabled
- Gop size—Frequency of periodic intra (or IDR) pictures in the encoded stream output
- Slice enable/disable, slice size mode and slice size—Slice mode enable or disable as well as the slice size and size mode (number of bits or number of Mbytes in each slice)
- Output report such as sliceReport, mbReport and qpReport, and so on. qpReport option is only supported in H.263/MPEG-4 encoders—Informative output data such as slice boundary, MB boundary in encoded bitstream
- Miscellaneous options such as enableAutoSkip and intraRefresh—Enable auto-skipping of pictures when the output bit count is large enough as well as enable intra-refresh for error robustness and the number of intra MB in a non-intra picture
- Ring buffer mode enable, allows streaming mode setting for each encoder instance independently—Application decides whether a ring-buffer based streaming scheme is used or not. When this option is disabled, a frame-based streaming scheme is used with a line-buffer scheme
- Dynamic buffer allocation enable—Application allocates the picture stream buffer dynamically by enabling dynamic buffer allocation only if ring-buffer mode is disabled. If dynamic buffer allocation is disabled, the address and size of the bitstream buffer is used in picture encoding. If dynamic buffer allocation is enabled, the address and the size of picture stream buffer is dynamically given by the application while issuing the picture encoding operation.
- Intra quantization step—Intra Qstep value is configurable by specifying this value greater than 0. Even if rate control is enabled, the VPU encoder uses this fixed quantization step for all I-frames. This intra quantization step is re-configurable after creating an instance dynamically.
- Video standard specific parameters—Specify standard-specific parameters for each video codec standard such as error resilience tools in MPEG-4, Annexes in H.263, deblocking and FMO parameters in H.264, source chroma format and thumbnail parameters and table coefficients in MJPEG and so on.

Using these options, the application receives a well optimized output for the requirements of the target application. Some output information options such as sliceReport, mbReport, qpReport, and so on, help application developers satisfy the constraints for target applications.

For example, for a fixed packet size, an application might need to insert one slice to a certain amount of bits. If the slice size is given by the number of bits, it does not ensure that the output slice size is smaller than the given size because of the variable length characteristics of the encoding process. Therefore, the application divides the slice into two packets which causes an inefficiency in the packetization. To achieve an easy packetization, the application sets the slice size to (packet\_size - N) with a certain margin of N, which allows the output slice size to be less than the packet size. Then the application easily adds a slice into a packet by referring to the slice boundary information provided by the VPU as encoder output.

MJPEG can be encoded with various YUV format such as 4:4:4 by setting source format variable. 4:0:0, 4:2:0, 4:2:2 horizontal/vertical and 4:4:4 formats are supported in the i.MX51 MJPEG encoder. The i.MX51 VPU also supports encoding using a user defined Huffman Table and Q matrix. To encode using a user defined Huffman Table and Q matrix, the host must save the coefficients in a pre-defined format and set the pointer to the area.

After creating an encoder instance with these parameters, the application cannot change these parameters. If the application wants to change any of these basic parameters, it should close this instance and re-create another encoder instance with new initial parameters. However, the application may need to change some of these initial parameters depending on the target application environment. Using the dynamic configuration command, the VPU API enables the application to configure part of these initial parameters dynamically. For details, refer to [Section 3.3.3.9, “vpu\\_EncGiveCommand\(\).”](#)

The API function, **vpu\_EncOpen()**, does not require any operations on the VPU side but declares all of the internal parameters used in later stages as well as the bitstream buffer information.

## 4.2.2 Configuring VPU for Encoder Instance

### 4.2.2.1 Sequence Initialization

After registering all of the required information for the new encoder instance, the host application configures the VPU to support the new encoder instance. This procedure is completed by setting the encoder related information in the VPU host interface registers and giving a command, ENC\_SEQ\_INIT, to the VPU for initiating the internal configuration operation in the VPU.

This process is mainly completed by an API function, **vpu\_EncGetInitialInfo()**, and this function return a crucial output parameter for encoder operations, the minimum number of frame buffers. Normally, this process does not require much time, and it should be done only once at the beginning of each encoder instance. Therefore, it is not recommended to use an interrupt signal for this function, but interrupt signaling is allowed after completion of this operation by enabling the corresponding bit on interrupt enable register.

### 4.2.2.2 Registering Frame Buffers

The configuration process is completed by registering the frame buffers to the VPU for picture encoding operations. In this final stage of configuration, the parameter returned from **vpu\_EncGetInitialInfo()**, the minimum number of frame buffers, has an important meaning. This parameter means that the application should reserve at least the same number of frame buffers to the VPU for proper encoding operation. For MJPEG, the frame buffer is not necessary, because MJPEG does not need motion compensation. Therefore, only the frame buffer stride is transferred to the VPU in this stage. The stride value is used as the stride of the source image frame buffer.

### 4.2.2.3 Generating High-Level Header Syntaxes

Automatic header syntax generation (such as VOL in MPEG-4, SPS/PPS in AVC) is not supported.

When the encoder instance has been opened by calling **vpu\_EncGetInitialInfo()**, the application generates the high-level header syntaxes such as VOS/VO/VOL headers in MPEG-4 and SPS/PPS in AVC

from the VPU using **vpu\_EncGiveCommand()**. These high-level syntaxes can also be used directly for negotiation in the transport protocol layer of the application.

There are two possible methods for generating these header syntaxes: by **PARA\_BUF** or by the stream buffer. The recommended way for generating the header syntaxes is to use the **ENC\_PUT\_AVC/MP4\_HEADER** command by the stream buffer. If the application uses this set of commands, the resulting header syntaxes are stored into the bitstream buffer according to the given endian setting.

If **DecBufReset** is enabled, the output header syntaxes are written to the bitstream buffer starting from the base address of the bitstream buffer. If the application does not read out each header syntax one-by-one, they are overwritten by the following header syntaxes. If the application wants to read out a set of header syntaxes (such as **VOS/VO/VOL** or **SPS/PPS**), then the application should disable **DecBufReset** and enable the **DecBufFlush** bit. After completing the generation of the last header syntax, the application can read out a cascaded set of header syntaxes together.

The other method for generating header syntaxes, by **PARA\_BUF**, is used when the application wants to generate header syntaxes in the middle of encoding. It can be accomplished using **ENC\_GET\_XXX\_HEADER** for **MPEG-4**, and **ENC\_GET\_XXX\_RBSP** for **AVC**. Regardless of the streaming mode, this command generates header syntaxes successfully, but the endian setting is always big endian. So for little endian systems, an endian conversion should be performed.

## 4.2.3 Running Picture Encoder on VPU

### 4.2.3.1 YUV Input Loading

Before running a picture encoder operation, the host application should provide a 4:2:0 or 4:2:2 vertical formatted input YUV image with a pre-defined size for **H.263**, **MPEG-4** and **H.264**. The host should provide 4:2:0, 4:2:2 vertical/horizontal, 4:4:4 or 4:0:0 formatted input YUV for **MJPEG**. If the input image is coming from an external video input device, such as a **CMOS** sensor, the VPU idles while waiting for completion of the receiving input picture. To avoid this idling, use a dual buffering scheme for the input image so that the encoder does not spend any cycles idling before starting operation.

### 4.2.3.2 Initiating Picture Encoding

When activating picture encoding operations, the application provides the following information to the VPU:

- Source frame address—Base address of each component of input YUV picture
- Quantization step—for the current picture which is ignored when rate control is enabled
- Forced frame skip and forced I-picture options—Forced frame skip is skipping the current frame encoding unconditionally and force I-picture is encoding current frame as I-frame unconditionally
- Source format—The VPU supports 4:2:2 vertical format source image. The source image is converted to 4:2:0 format automatically

After providing this information to the VPU, the host processor initiates a picture encoding operation by sending a **ENC\_PIC\_RUN** command to the VPU.

These processes can be performed by calling a single API function, **vpu\_EncStartOneFrame()** with the **EncParam** structure. This API function initiates a picture encoding operation. Return from this API does not mean that picture encoding is completed, only that the encoding operation began successfully.

The quantization step size given to the VPU with **ENC\_PIC\_RUN** is only meaningful when the rate control option is disabled. This additional feature is provided to support application-specific VBR encoder operations.

The forced frame skip option is used when encoding a new picture is not allowed temporarily. Automatic frame skipping in the VPU rate control is used for limiting the output amount of the bitstream under the given target bit-rate. Also, the forced frame skip can be used by the application when encoding a picture is problematic under certain external situations, for example, if the channel condition is temporarily unacceptable and transmitting the encoded stream is impossible. Then the application can suspend the encoder operation for a while using this forced frame skip option.

The forced I-frame option is used when the remote receiver side reports an error during decoder operation. Even though a certain error concealment or error robustness scheme might be implemented on the decoder side, the best way to recover from a decoder error is to send an I-frame. Using this forced I-frame option, the application can achieve error-recovery of the remote receiver side very effectively.

#### 4.2.3.3 Completion of Picture Encoding

Picture encoder operation takes a certain amount of time and the application can be completing other tasks while waiting for the completion of picture encoding operation, such as packetization of the encoded stream for transmission. The application can use two different type of schemes for detecting completion of the picture encoding operation: polling a status register or interrupt signaling. When the application is using a polling scheme, the application checks the **BusyFlag** register of the **BIT** processor. Calling **vpu\_IsBusy()** gives the same result.

Interrupt signaling can be the most efficient way to check the completion of a given command. An interrupt signal for the **ENC\_PIC\_RUN** command is mapped on bit 3 of the interrupt enable register. Therefore, the application can use this dedicated interrupt signal from the VPU to determine the completion of the picture encoder operation.

#### 4.2.3.4 Encoder Stream Handling

When the encoder stream buffer is large enough to store any size of picture stream, the encoder does not need to retrieve any bitstream data during the picture encoder operation. After the encoder operation is complete, the host application reads the encoded bitstream according to the requirements of packetization.

When the encoder stream buffer is not large enough to store a complete picture stream, the encoder buffer-full occurs and until this buffer-full situation is resolved, the encoder task running on the VPU is stalled. Therefore, while the picture is encoding, the application should continue reading out the encoded bitstream from stream buffer to avoid this stalling.

When using a ring-buffer scheme with a limited size of encoder stream buffer, stream reading during encoder operation is recommended. Using two dedicated functions, **vpu\_EncGetBitStreamBuffer()** and **vpu\_EncUpdateBitStreamBuffer()**, the application can easily handle the read pointer while accessing the encoder bitstream buffer. If the ring-buffer option is disabled with a stream buffer large enough to store

one encoded picture data, the host can wait to read the encoded bitstream at the end of each picture encoding. In this case, the application can safely complete other tasks while the picture encoding is running on the VPU. The **vpu\_EncGetBitStreamBuffer()** and **vpu\_EncUpdateBitStreamBuffer()** functions have no meaning when the application uses the frame-based streaming option.

### 4.2.3.5 Acquiring Encoder Results

When picture encoding is complete, the host application retrieves the encoded output such as the encoded picture type, number of slices, and so on. According to the input parameter settings of the picture encoding, the slice boundary and MB boundary information can also be acquired from the VPU. For H.263/MPEG-4 decoding, the MB Qstep information can be acquired from the VPU. This encoder output information is generally placed on the parameter buffer with pre-defined formats (for the predefined formats of the output information, refer to the *i.MX51 Applications Processor Reference Manual*). Therefore, the application can read out this information directly from the parameter buffer using the base address of each data structure.

The VPU API provides a function for retrieving the output results of the picture encoder, **VPU\_EncGetOutputInfo()**, which has a output data structure that includes the following information:

- Start address of encoded picture and its size
- Number of slices in the encoded picture
- Slice boundary information in the encoded bitstream
- MB boundary information in the encoded bitstream
- Application-specific information for packetization such as MB Qstep information

Some packetization schemes, such as Real-time Transfer Protocol (RTP), require some internal information of encoded picture depending on the codec standard.

The slice information is useful for packet-based applications which have limitations of the slice start in the video packet. The slice information is also useful for implementing slice re-ordering on the application side such as Arbitrary Slice Ordering (ASO) in the H.264 standard.

The VPU API includes a constraint on using the encoder initiation function and the encoder result acquisition. When using the VPU API, the application should always use these two functions as a pair. This means that without calling the result acquisition function, **vpu\_EncGetOutputInfo()**, the next picture encoding operation is not initiated by calling **vpu\_EncStartOneFrame()**. Most VPU commands are not allowed unless the application calls **VPU\_EncGetOutputInfo()** after completion of the picture encoding operation. This constraint is used to protect the encoded results from being overwritten from another thread by mistake in a multi-instance environment. Therefore, the application should regard the **vpu\_EncGetOutputInfo()** function as a releasing command of the VPU from the current picture encoding operation.

### 4.2.4 Terminating an Encoder Instance

When the application finishes with the encoder operation and terminates an encoder instance, the application releases the handle of this instance to inform the VPU that this instance is terminated by giving the SEQ\_END command to the VPU. This can be accomplished by calling **vpu\_EncClose()** function.

## 4.2.5 Dynamic Configuration Commands

While running sequential picture encoding operations, the application may need to give special commands to the VPU such as rotating the input pictures before encoding, inserting a high layer header syntaxes, and so on. The VPU API provides a set of commands to support the following special requests from the host application:

- Rotate and mirror source frame before encoding
- Extract high layer header syntaxes such as VOS/VO/VOL in MPEG-4 and SPS/PPS in H.264 for external use
- Insert high layer header syntaxes such as VOS/VO/VOL in MPEG-4 and SPS/PPS in H.264
- Change encoder parameters such as bitrate, frame rate, GOP number, slice mode and so on dynamically between picture encoding operations

## 4.3 Decoder Control

### 4.3.1 Creating a Decoder Instance

After initialization of the VPU, the next step to run a decoder operation is to create a decoder instance and acquire a handle for specifying that decoder instance. This is accomplished using a single API function, **vpv\_DecOpen()**.

When creating a new decoder instance, the application specifies the internal features of this decoder instance through the DecOpenParam structure. This structure includes the following information about the new decoder instance:

- Bitstream buffer address and size—Physical address of bitstream buffer start address and its size
- Codec standard—Video codec standard such as H.263, MPEG-4, H.264 or VC-1
- MPEG-4 deblocking filter enable—Enable or disable MPEG-4 deblocking filter option
- ReorderEnable—Enable or disable H.264 display reordering option, this option is ignored for other decoder standards. It should usually be set to 1.
- File-play mode enable and picture size information—Enable or disable frame-based streaming option for local file-play mode. The application allocates the picture stream buffer dynamically by enabling dynamic buffer allocation. If dynamic buffer allocation is disabled, the address and size of the bitstream buffer is used in picture decoding. If dynamic buffer allocation is enabled, the address and the size of the picture stream buffer is given dynamically by the application while enabling the picture decoding operation. Using the start byte-offset, the host application eliminates the limitation for 8-byte alignment of the bitstream buffer.
- Picture size information—Picture size information is used only if file-play mode is enabled. This information can be read from the file-format and is generally included in stream header itself. Therefore, it is not necessary to give this information for file-play mode. But this field is available for general usage of file-play mode. The given picture size information is ignored when the bitstream includes the decoded picture size.
- SPS/PPS RBSP save buffer address and size—Physical address and size of buffer for SPS and PPS

- Enable thumbnail decoding of MJPEG—Enable thumbnail decoding. If the host enables thumbnail decoding, the decoded output is a thumbnail

For decoding, most information is acquired from the input stream, so there are few required parameters for creating a decoder instance. The VPU API function, **VPU\_DecOpen()**, does not require any operations on the VPU side but declares all the internal parameters to be used in later stage as well as the bitstream buffer information.

### 4.3.1.1 AVC Display Reordering

The AVC-specific display reordering option should be used carefully, because it drastically varies the behavior of the AVC decoder. In principle, this option should always be enabled because the flag for this option is embedded in the header syntax. According to the options in the header, the required frame buffer size is automatically determined by the VPU.

When creating a decoder instance for H.264, the application should decide if display reordering is used. In principle, this bit field should be set to 1, because the display reordering option is enabled or disabled automatically according to the values of the corresponding header fields. But in practice, there are too many streams which do not actually use display reordering but display reordering option is enabled.

Display reordering generally requires many more decoder buffers, a much longer delay, and some complex constraints in decoder operations. When display reordering is not used even though the display reordering option is enabled on the baseline profile stream, sometimes it would be helpful for application to force the VPU decoder to ignore this option. This flag is provided for this case.

When this option is disabled, the minimum number of frame buffers is reference frame number + 2. Whenever one frame decoding is complete, a display (or decoded) output is provided from the VPU, so the decoder operation is the same as a normal decoder operation.

But when this option is enabled, the minimum number of frame buffers is  $\text{MAX}(\text{reference frame number}, 16) + 2$  for the worst case. After decoding one frame, the VPU cannot provide a display output because display order can be different from the decoding order. In the worst case, the first display output is provided from the VPU after decoding 17 frames. Because of this characteristic of display reordering, the VPU AVC decoder always decodes display delay + 1 frames during the first call of the picture decoding when display reordering is enabled in the stream.

In practice, there are many streams which do not use display reordering, but the flag in the header is enabled. In this case, the host application must allocate unnecessarily more frame buffers and apply large delays. Considering this practical cases, this option for forced-disable of display reordering is provided in the VPU API.

## 4.3.2 Configuring VPU for Decoder Instance

### 4.3.2.1 Feeding Bitstream into Stream Buffer

For the decoder, sequence initialization performs parsing of high level header syntaxes such as VOS/VO/VOL in MPEG-4 and SPS/PPS in H.264 for reading out decoder configurations. To start sequence initialization, the application fills the decoder stream buffers with enough bitstream data. In some

applications, the host applications can not guarantee that those kinds of header syntaxes are placed at the beginning of the bitstream. In this case, until the VPU successfully receives all of the required information from the input stream, the application should keep feeding the input data stream to the decoder bitstream buffer.

In file-play mode for MPEG-4 and H.264, **vpv\_DecGetInitialInfo()** operates only with sequence level header syntaxes (VOS/VO/VOL headers or SPS/PPS), which might be much smaller than the 512 byte minimum transfer unit. Because of the start-codes in these codec standards, reinsertion of the header data does not cause any problems while decoding the first picture. So the application can also use dynamic buffer allocation with the same buffer start address for the first picture decoding.

In file-play mode of VC-1, SEQ\_META, FRAME\_META and chunk data should be fed into the stream buffer before calling **vpv\_DecGetInitialInfo()**. Inserting only the SEQ\_META information is not allowed in this case because the VC-1 MP standard does not use start-codes. For dynamic allocation, the VPU decoder does not use the new buffer start-address, but instead uses the previous buffer pointer updated by **vpv\_DecGetInitialInfo()** because of this limitation. For the second picture decoding, FRAME\_META and a chunk of data placed at a different buffer can be used in dynamic allocation.

To feed the input bitstream, the host application should know the available space in the bitstream buffer. This is determined using the read pointer, write pointer and stream buffer size because the stream buffer operates as a ring-buffer. Getting the available space in the stream buffer, the application can directly download the decoder input stream to the bitstream buffer. After completing the stream download, the application informs the amount of downloaded stream data by updating the stream write pointer.

The VPU API provides an API function to get the stream read pointer, write pointer and available space, **vpv\_DecGetBitstreamBuffer()**. Updating the write pointer is accomplished using the API function, **vpv\_DecUpdateBitstreamBuffer()**.

### 4.3.2.2 Sequence Initialization

After creating a new instance and feeding the input bitstream to the stream buffer, the application gives the DEC\_SEQ\_INIT command to the VPU to get the decoder configuration information from the bitstream. After parsing the header syntaxes, the decoder returns the following crucial information about the decoder configuration:

- Picture size—Picture width and height
- Frame rate—Decoder frame rate
- Picture cropping rectangle information—Information about H.264 decoder picture cropping rectangle which is the offset of top-left point and bottom-right point from the origin of frame buffer
- Minimum number of frame buffers
- MPEG-4 option information—Enable or disable MPEG-4 error resilience options such as data partitioned or Reversible VLC as well as short video header mode
- Frame buffer delay for display reordering—The number of frame delays for supporting display reordering in H.264 decoder
- Annex-J (Deblocking) option indication—This flag indicates whether the deblocking option of the H.263 decoder is enabled or disabled. When the external post-deblocking filter is used for H.263,

this flag is used to avoid repetition of the H.263 in-loop deblocking filter and external post-deblocking filter

- Number of returned next decoded index after decoding one frame—The number of returned indexes which are used in next decoding after decoding one frame
- Estimated slice save buffer sizes—The size of the slice save buffer. The VPU reports two different sizes: recommended and worst-case
- MJPEG thumbnail enable information—This flag indicates whether thumbnail image of MJPEG exists or not. When thumbnail does not exist in the stream, the VPU returns failure if the host application enables the thumbnail decoding option
- MJPEG image YUV format—Image YUV format. The host must allocate frame buffer by this value

The picture size acquired from the bitstream might not be a multiple of 16×16. However, to perform the decoder operation properly, frame buffer size should be a multiple of 16×16. Therefore, the returned size is modified to be a multiple of 16×16 after a ceiling operation. Using the picture size and the minimum number of frame buffers, the application reserves frame buffers and provides them to the VPU before starting the picture decoding operation.

The frame buffer delay is an H.264-specific parameter for supporting display reordering. If the application supports display reordering and reordering requires five additional frame buffers, for example, then the first display output comes out from decoder after decoding the 6<sup>th</sup> frame. Theoretically, the maximum delay for display reordering is a 16-frames.

The VPU API provides a function to handle the DEC\_SEQ\_INIT operations, **vpu\_DecGetInitialInfo()**. Completion of this function is signaled by a dedicated interrupt or by polling the BusyFlag.

An important issue in SEQ\_INIT operation is error-handling because any errors in the high layer header syntaxes cause serious problems in decoding operations. Generally, many marker bits are added to the header syntaxes to assist error detection. When header syntaxes included in the stream have crucial errors, or when header syntaxes are not received for a long time, the VPU can be stuck on this task and no other instances can run on the VPU. Therefore, the VPU API provides a special function which is used in this situation, called **vpu\_SetSeqInitEsc()**. When this function is called and the stream buffer is empty, the VPU automatically terminates the SEQ\_INIT operation. Then the host application decides whether to close this instance or retry SEQ\_INIT after running a different codec instance. After escaping from this situation, it is highly recommend to reset the internal ESCAPE flag by calling the **vpu\_SetSeqInitEsc()** function again. This flag affects all the decoder instances performing a DEC\_SEQ\_INIT operation.

### 4.3.2.3 Registering Frame Buffers

This configuring process is completed by registering the frame buffers to the VPU for picture decoding operations. In this final stage of configuration, the parameter returned from **vpu\_DecGetInitialInfo()**, the minimum number of frame buffer, has an important meaning. This parameter means that the application should reserve at least the same number of frame buffers to the VPU for proper decoding operation.

The size of the frame buffers is calculated from the picture width and height. When both the picture width and height are a multiple of 16, the picture size is the size as the frame buffers. If both the picture width

and height are not a multiple of 16, the application should apply a ceiling operation to the picture width or picture height to get the smallest multiple of 16 larger than picture width or picture height.

In addition to registering the frame buffers to the VPU, the slice save buffer is also registered in this step. The recommended buffer size is given by calling **vpu\_DecGetInitialInfo()**.

For MJPEG decoder, registering the frame buffers is not necessary. The MJPEG decoder uses rotation decoding. If **vpu\_DecRegisterFrameBuffer()** is called, no operations are performed.

### 4.3.3 Running Picture Decoder On VPU

#### 4.3.3.1 Initiating Picture Decoding

When activating a picture decoding operation, the application provides the following information to the VPU:

- Pre-scan Enable—Enable or disable pre-scan option for checking whether full picture stream exists in the stream buffer
- Pre-scan Mode—Specify decoder operation mode after pre-scan
- I-Frame Search Enable—Enable or disable I-(IDR for H.264) frame search option
- Frame Skip Mode—Enable or disable skipping bitstream for the next frame decoding
- picStreamBufferAddr and picStartByteOffset—Start address of the picture stream buffer to be decoded in file-play mode and the byte offset of the actual start bytes of the picture data
- chunkSize—Byte size of the picture stream to be decoded which is read from the file-container information

After providing these parameters to the VPU, the application starts the picture decoding operation by sending a DEC\_PIC\_RUN command.

The pre-scan option is a special option for scanning the bitstream buffer to check if a full picture stream exists in the stream buffer. This option allows the application to determine whether the bitstream empty and decoder stalls or not before running the actual decoder operation. When this option is enabled and there is not a full picture stream in the decoder buffer, the DEC\_PIC\_RUN command does not initiate the picture decoding operation and returns immediately. Then the application decides whether to retry the picture decoding after feeding more bitstream data or to handle other tasks for a while.

The pre-scan mode is also given as an option for general usage of the pre-scan operation. When this flag is set to 0 and there is at least one full picture stream in the stream buffer, the decoder operation is automatically initiated. On the contrary, when this flag is set to 1, the DEC\_PIC\_RUN command returns immediately with a return code representing whether a full picture stream exists or not. In this case, no picture decoding is initiated. To run picture decoding in this case, the application resets this flag to 0 and re-sends the DEC\_PIC\_RUN command.

When display reordering in H.264 is enabled, the first decoded output is only available after decoding many frames. To avoid this, a constraint is added to the H.264 decoder that requires the decoder to fill all the reordering display buffers at the first time of picture decoding. That means, if the frame buffer delay received from the stream header is five, the H.264 decoder should decode six frames at once at the first DEC\_PIC\_RUN operation. Then, the picture decoding always provides a picture output to be displayed.

In this scenario, the pre-scan might cause problems, because it is designed for the case of one picture decoding. So when display reordering is enabled, it is recommended that the first DEC\_PIC\_RUN be performed with pre-scan disabled.

To support display reordering in H.264 mode, a special parameter is used to flush the stored decoder output from the display reorder buffer without picture decoding. This option is designed for flushing out the decoded picture not yet displayed at the end of the decoding video sequence. When the display reordering option is enabled and the reordering frame buffer stores five decoded pictures, the first display output is available after the 6<sup>th</sup> frame decoding. Therefore, at the end of the stream decoding, there are five decoded pictures which are not displayed yet even though there is no more available bitstream data to decode. In this case, the application may ignore these five non-displayed pictures or display them by setting the dispReorderBuf parameter to 1 and sending the DEC\_PIC\_RUN command until the VPU returns the decoded picture index of -1.

In file-play mode, the decoder refers the start address of the picture stream from picStreamBufferAddr given with the DEC\_PIC\_RUN command or BitStreamBuffer given with the DEC\_SEQ\_INIT command depending on the dynamicBuffAllocEnable setting. When dynamicBuffAllocEnable is set, the stream buffer information, BitStreamBuffer, specified during DEC\_SEQ\_INIT is ignored. The size of the picture stream always refers chunkSize given with the DEC\_PIC\_RUN command.

It is necessary for the application to read this chunk size from the file format header for every frame processing. The application might use dual or multiple picture stream buffers for speed optimization or might also use dynamic allocation for better memory management with the dynamicBuffAllocEnable option. In file-play mode, the application can achieve higher efficiency of stream buffering and memory management with dynamic buffer allocation.

#### NOTE

There might be empty chunks whose chunk size equals zero. These empty chunks should be removed in the file format parser because they might cause improper operations in the VPU.

The VPU API provides an API for handling all these complex operations, **vpu\_DecStartOneFrame()**, which initiates the picture decoding operation and returns as soon as picture decoding has started on the VPU. Completion of picture decoding is checked using a different method.

### 4.3.3.2 Frame Skipping Option

When a decoder error is detected, the application might want to hide the corrupted decoder output. Even though error concealment is applied to that decoder output, some applications would like to freeze display instead of showing the corrupted picture. This output-hiding operation should continue until the decoder meets the next I (or IDR) frame. Considering AV synchronization, skipping one frame can be a good way to hide a sequence of pictures without affecting the audio decoding operation.

The frame skipping option is supported for the picture decoding command. As well as skip enable or disable, the skipping option of detecting an I (or IDR in H.264)-frame can be chosen by the application. So when an error is detected during picture decoding and the application would like to hide the error-defected pictures, the application can achieve this using the picture skipping option with I-frame detection enabled. By setting skipframeMode of DecParam to 1, the application easily performs skipping

of non-intra (or non-IDR) frames. While the application enables one frame skipping by setting skipframeNum of DecParam to 1, pre-scan is automatically enabled and therefore, the frame skip result is translated to a pre-scan result. While doing one frame skip, the application can detect the results of the frame skipping by checking prescanresult of DecOutputInfo.

This frame skip feature can be used by the application when the system performance is temporarily degraded and video decoding is significantly delayed. In this case, it is recommended for the application to use the I-(IDR in H.264 case) frame detect option. Using this option, the application can only decode I-(or IDR) frame properly without displaying error-defected frame output.

Multi-frame skipping is also supported by setting skipframeNum of DecParam greater than 1. But multi-frame skipping is not recommended in normal usage because it may cause problems with AV synchronization.

In file-play mode, frame skipping can be easily achieved in the application side by referring the file format header syntax. Therefore, it is not required to support this feature in the frame-based streaming case. But in the random access case, the I-frame search option can be useful when the keyframe information in the file container is incorrect.

#### 4.3.3.3 I-Frame Search for Random Access and Trick Mode

When a media player application is designed, trick modes and random access may be desirable features. To achieve these operations the application, decoder should support a feature for searching the I-frame in the middle of the decoder bitstream.

The I-frame search option is accomplished by setting the iframeSearchEnable of DecParam. The number of I-frames skipped is also set by setting skipframeNum of DecParam. (The same skipframeNum of DecParam is used for specifying the skipped frame number in frame skipping and I-search; however, the meaning of this value is somewhat different.) If skipframeNum = N, all the intermediate frames before the (N+1)<sup>th</sup> next I-frame are skipped. This multiple I-frame skipping might be used for high speed playback such as fast forward. By increasing the number N, the application can increase the speed of the fast forward. This kind of fast forward operation depends on the frequency of the I-(IDR) frames in the decoder input bitstream. Therefore, this type of trick mode can be applicable to applications specifying the maximum interval between I-frames.

Random access is generally supported with a form of slide-bar in a graphic user interface of a player. For supporting this random access, an I-(or IDR in H.264) frame search operation is needed because decoding intermediate inter-frames causes visual artifacts on displayed pictures. As well as I-frame search functionality, random access also requires a buffer-reset scheme that does not cause unexpected artifacts in the decoded output. The steps of random access for the video decoder are as follows:

1. Freeze the display and reset the decoder bit-stream buffer
2. Read the bitstream from the new file read pointer and transfer it into the decoder
3. Enable I-Search and run the picture decoding operation
4. If the buffer empty interrupt is signaled, feed more bitstream and wait for decoding completion
5. If decoding completion is detected, read the decoder results and resume display

Resetting the bitstream buffer in Step 1 can be accomplished by calling **vpu\_DecBitBufferFlush()**. Starting the decoder operation with I-frame search can also be accomplished by calling

**vpu\_DecStartOneFrame()** with `iframeSearchEnable` of `DecParam` set to 1. The number of skipped frames specified by `skipframeNum` of `DecParam` is given by 1 in random access operation. When an interrupt of decoder completion or non-busy state of the BIT processor is detected, the I-frame is searched and decoded.

When the application uses the I-frame search option, the decoder should skip many bits in the decoder stream buffer. Therefore, the pre-scan option can be meaningless when used simultaneously with the I-search. In the VPU firmware; therefore, the pre-scan option is automatically disabled and settings for the pre-scan option are ignored. The application should handle stream buffer filling until the end of the I-search operation. Larger stream units are recommended in this case; otherwise, too many stream buffer empty interrupts might occur from the VPU side.

#### 4.3.3.4 Decoder Stream Handling

When the decoder stream buffer includes a full picture stream, the host application does not need to worry about streaming in the middle of the decoder operation. Using the pre-scan option, the application can determine the status of the bitstream buffer in advance. If there is no full picture in the stream buffer, the application might feed more stream data to the stream buffer and start the picture decoding operation.

The VPU API provides an API function to get the stream read pointer, write pointer and available space in one function call, **vpu\_DecGetBitstreamBuffer()**. The application can get the information about the available space in the stream buffer using this API and transfer an amount of stream data to the stream buffer which is less than or equal to the available size. When transferring the stream data, the application should take care of the end of the stream buffer to avoid unexpected data corruption. When transferring stream data to the stream buffer and the write pointer reaches the end of the stream buffer, the application should wrap the write pointer around to the beginning of the stream buffer and then continue downloading to avoid data corruption.

Updating the write pointer is accomplished using **vpu\_DecUpdateBitstreamBuffer()**. The write pointer wrap-around and updating of the write pointer is done by this API function by providing the downloaded stream size. Before updating the write pointer, the host application must finish transferring the stream data to the stream buffer. If not, a mismatch in access time may cause problems in the decoder operation.

In file-play mode, the two APIs for streaming are meaningless because the VPU always assumes the bitstream buffer is flushed at the end of every picture decoding operation. The application only needs to feed the stream buffer with one frame stream and then call **vpu\_DecStartOneFrame()**.

#### 4.3.3.5 Completion of Picture Decoding

Picture decoder operations take a certain amount of time, and the application can complete other tasks while waiting for the completion of the picture decoding operation, such as display processing of the previously decoded output. The application can use two different schemes for detecting the completion of the picture decoding operation: polling a status register or waiting for an interrupt signal. When the application uses the polling scheme, the application checks the BusyFlag Register of the BIT processor. Calling **vpu\_IsBusy()** gives the same result.

Interrupt signaling can be the most efficient way to check the completion of a given command. An interrupt signal for the `DEC_PIC_RUN` command is mapped to bit 3 of the interrupt enable register. So

the application can easily determine the completion of the picture decoder operation from this dedicated interrupt signal from the VPU.

#### 4.3.3.6 Acquiring Decoder Results

When picture decoding is complete, the host application retrieves the decoded output, such as the display frame index, decoded frame index, decoded frame picture type, number of error concealed MBs, Pre-scan result, and so on. The VPU API provides a function for retrieving the output results of the picture decoder, **vpu\_DecGetOutputInfo()**.

The VPU API includes a constraint on using the decoder initiation function and decoder result acquisition. When using the VPU API, the application should always use these two functions as a pair. This means that without calling the result acquisition function, **vpu\_DecGetOutputInfo()**, the next picture decoding operation is not initiated by calling **vpu\_DecStartOneFrame()**. This constraint is used to protect the decoded results from being overwritten from other thread by mistake in multi-instance environment. Therefore, the application should regard **vpu\_DecGetOutputInfo()** function as a releasing command of the VPU from the current picture decoding operation.

#### Reading Display Output

The display frame index, `indexFrameDisplay`, is used to represent the frame buffer number where the display output picture is stored. It always equals the frame buffer index to be displayed and it can be different from the decoded picture index when display ordering control is enabled, such as display reordering of H.264, B-frame in VC-1, and so on.

At the beginning of sequence decoding, even after decoding several frames, there is no display output from decoder because of the order of display. For H.264 reordering, in worst case, the first display output can come out after the 17<sup>th</sup> frame decoding. Therefore, at times there is no proper display buffer index. In this case, the VPU decoder returns a negative frame buffer index for `indexFrameDisplay` of `-3` or `-2` depending on the frame skip option. Only at the end of sequence decoding is this value equal to `-1` and the application can terminate the current decoder instance without any loss in picture display. [Table 7](#) shows the display output status based on the `indexFrameDisplay` values.

**Table 7. indexFrameDisplay Values**

<b>indexFrameDisplay Value</b>	<b>Display Output Status</b>
Non-negative value	Output index value points to the frame buffer index of the display output
-1	Signals the end of sequence decoding, there is no more display output when the stream end is signaled to the VPU
-2	There is temporarily no display output because of the frame-skip option
-3	There is temporarily no display output even without any action by the host application. Usually, this value occurs when an IDR picture is received for H.264 display-reordering mode

#### Reading Decoded Output

The decoded frame index, `indexFrameDecoded`, is an optional output to the host application. This index is used to represent the frame buffer number where the decoded picture is stored. Usually, the host

application does not need to worry about this index. The display index, `indexFrameDisplay`, is sufficient to handle the output of the VPU decoder. Under this situation, this value is equal to `-2 (0xFFFFE)` to represent that there is no decoded frame at this time. This negative decoded index is also used when picture decoding is skipped because of a skip option or picture header error.

When there are not enough frame buffers to be written with decoded image data, this value is equal to `-1 (0xFFFF)`. In this situation, the application re-calls `vpu_DecStartOneFrame()` after clearing the display flag by calling `vpu_DecClrDispFlag()`.

When display ordering control is enabled for H.264 display reordering, VC-1 B-frame, and so on, at the end of sequence decoding, the host application needs to flush out the decoded frames for display. During this flushing operation, no actual decoding operations are performed. Under this situation, this value is equal to `-1 (0xFFFF)` to represent that there is no decoded frame this time. This negative decoded index is also used when picture decoding is skipped because of skip option or picture header error.

## Reading Pre-Scan Result

The pre-scan result flag represents whether a full picture stream is included in the bitstream buffer before picture decoding. When this flag is equal to 0, the decoding operation is not performed because there is no full picture stream in the stream buffer. If application enables pre-scan and sets pre-scan mode to 0 (decoding a picture when full picture stream exists), the application should check this output parameter first to determine whether a decoding operation is performed or not.

When pre-scan result is 0 and the stream buffer is full and the current stream buffer is too small to store a full picture stream. To avoid dead-lock, the host application should disable the pre-scan option and re-run the picture decoding operation.

## Display Cropping in H.264

The display cropping option in H.264 forces the host application to display part of the frame buffers. The information about the cropping window is provided by SPS. In SPS, four offset values of cropping rectangles are presented, and these four offset values are given by the `picCropRect` structure to the host application. Using these four offset values, the host application can easily detect the position of the target output window. When display cropping is off, the cropping window size is 0.

## Next Decoded Frame Index

The next decoded frame index, `indexNextFrameDecoded[3]`, is an optional output to the host application. This indexes are used to represent the frame buffer index which is used in the next `VPU_DecStartOneFrame()` call. The application might not stop calling `VPU_DecStartOneFrame()` to protect display corruption, if some of these indexes are not displayed yet.

When display ordering control is enabled for H.264 display reordering, VC-1 B-frame, and so on, at the end of sequence decoding, the host application needs to flush out the decoded frames for display. During this flushing operation, no actual decoding operations are performed. Under this situation, this value might be ignored.

## Reading Lack of Additional Work Buffer

The VPU reports the status of the PS (SPS/PPS) save buffer and slice save buffer after it decodes one frame. If the VPU reports lack of PS save buffer, the VPU can not properly decode the remaining input stream; therefore, it is best to close current instance in this situation. If the VPU reports lack of slice save buffer, the VPU can choose to either close and reopen the current instance or continue picture decoding regardless of display corruption until the next I-frame.

### 4.3.3.7 Management of Displaying Buffers Decoded

The VPU has flags to indicate if the frame buffer is displayed or not internally. The flag is set after the VPU returns the display frame index automatically and the VPU never uses the buffer for which the display flag is set. Before starting the decoding process, the VPU checks if there is a frame buffer available and returns immediately if there is no frame buffer to be written with decoded image with a current decoded index of -1. The host application clears the flag after completion of displaying the frame buffers by calling `vpu_DecClrDispFlag()`.

### 4.3.3.8 Escape from Decoder Hang

Even when pre-scan is used, it is still possible for an application to experience decoder hanging because of a stream error or lack of available stream at the end of sequence decoding. In the middle of picture decoding, decoder hanging is signaled to the application through the decoder buffer empty interrupt if this interrupt is enabled, and the application can avoid decoder hanging by putting more bitstream data to stream buffer.

In some extraordinary cases and at the end of sequence decoding, the application avoids decoder hanging by means of garbage insertion or sending an end-of-stream command to the VPU decoder. This is accomplished by calling `vpu_DecUpdateStreamBuffer()` with size of 0. As soon as the VPU detects this setting, the VPU terminates the current picture decoding with error concealment if applicable.

## 4.3.4 Terminating a Decoder Instance

### 4.3.4.1 Stream End and Last Picture in Stream Buffer

After the host application meets the end of stream and sends all of the stream data in the stream buffer, the host application must determine when the last picture output is coming out. If there is no display delay, this task is simple. But if display delay exists (reordering of the decoded pictures for display), this task might be difficult for the host application.

In the VPU API, a flag that indicates the end-of-stream is used. After sending the last byte of the stream data to bitstream buffer, the host application sets this flag and calls the `vpu_DecStartOneFrame()` function. After the last display output picture has come out, the decoded picture index is changed to -1. When the host application receives this index, host application detects the end of the sequence processing.

When the display delay exists (display reordering option in H.264, B-frames in other codecs), the host application gets the buffered decoder output frame even after finishing actual decoding operation. In this case, the host application calls the `VPU_DecStartOneFrame()` as usual. Until the delayed display output frames are completely flushed out, the VPU decoder provides the frame index of the newly displayed

output to the host application. And if there is no more available output, the VPU decoder returns a frame index of -1.

#### 4.3.4.2 Closing Current Instance

When the application finishes the last picture decoding operation and terminates a decoder instance, the application releases the handle of this instance and inform the VPU that this instance is terminated by giving the SEQ\_END command to the VPU. This can be accomplished by calling the `vpv_DecClose()` function.

#### 4.3.5 Dynamic Configuration Commands

While running sequential picture decoding operations, application may need to give a special command to the VPU. The VPU API provides a set of commands to support the following special requests from the host application:

- Rotate and mirror output frame before decoding
- Apply SPS and PPS from the external out-of-band protocol
- Specify the frame buffer address for the MPEG-4 deblocking filtered output

### 4.4 Example Applications

An example application can be found under `WINCE600\SUPPORT_PDK1_6\APP\VPV` after the i.MX51 BSP is installed. This application gives an example of how to use the decoder and encoder API to control the VPU hardware to implement an encoder and decoder. The `readme.txt` file under `WINCE600\SUPPORT_PDK1_6\APP\VPV\ENCTEST` and `WINCE600\SUPPORT_PDK1_6\APP\VPV\DECTEST` contains detailed information about how to build and run the example applications.
